With their development of concrete the Romans were able to produce a whole new style of architecture based on interior spaces rather than on the Greek ideal of external beauty. As a result, Roman architecture differs from Greek design in a number of very significant ways: the true arch, for example, was substituted for the classical Greek post and lintel, and the concrete vault was used as a means of enclosing a space with a continuous curve. In town planning, too, there were innovations: rather than using buildings as central focal points in surrounding open areas, as was the usual Greek manner, the Romans used their facades to limit open central spaces; the Greek temple, for example, was now placed on a high Roman podium and positioned to form one side of a colonnade that surrounded an open central court. The curve, which had been used infrequently in Greece, became a dominant element of Roman design: the rectan-

gular temple often became a rotunda and the square niche became a semicircular exedra. Finally, where the Greeks had used the natural landscape for the dominant setting of a temple or for the sloping seats of a theater, the Romans—whose architects were always engineers as well—created their own landscapes, by building (for one example) a free-standing theatrical structure, or by altering the natural topography to create a man-made balance and symmetry.

The use of the vault and dome in enormous structures is certainly the most memorable feature of imperial Roman engineering. This method of covering large halls was possible only after the perfection of concrete and the development of brick relieving-arches that formed the skeleton of the vault. Both the arch and barrel vault had been used long before in Mesopotamia and Egypt, and at Rome they became popular as early as the second century BCE. But it was principally in the imperial baths, palaces, and temples that the Romans perfected the technology of roofing great interior spaces. Stunning examples can be found in Italy (the palaces of the emperors on Rome's Palatine Hill and, most impressively, the dome of the Pantheon) and throughout the Romanized empire. Regrettably, we have almost no documentary evidence for the construction of these magnificent vaults, so the survival of the Pantheon is doubly important, first for the breathtaking elegance of its interior space, and because it gives us an unparalleled insight into the revolutionary methods of Roman imperial architects—a perfect combination of engineering and beauty.

Roman Developments in Mining Technology

During the Roman republic most important mineral resources were found in the Iberian Peninsula, which was rich in gold, silver, lead, copper, and iron. Other important sources of minerals were found in Britain, the Balkans, and Dacia.

The Romans practiced three main types of mining. Alluvial deposits of gold and tin were extracted by panning. Surface ores could be extracted through simple open-cast excavations. The Elder Pliny describes the process of hushing whereby water was diverted to wash away soil and rock from surface deposits. The water could also be directed through subterranean galleries to blast away parts of the mountain, a process that Pliny calls *ruina montium*. Aqueducts supplied water over a distance of 6 miles (10 kilometers) from the river Cothi to the gold mines at Dolaucothi in southern Wales. The flow of water was regulated by tanks placed on the slopes above the mines to enable a sudden release of water. Once the surface deposits were depleted, tunnels or shafts were dug to extract deeper veins of ore, requiring greater costs of labor, ventilation, and drainage. Remains of a wooden water wheel from Dolaucothi show that mechanical drainage was used, although Pliny says that manual draining was also employed (*Natural History* 33.97).

The Romans rarely developed new mining areas, instead expanding the scale of earlier operations. The scale of Roman operations is best

seen in the mining district of Las Médulas in northwestern Spain, where between 3.5 billion and 8.1 billion cubic feet (100 million and 230 million cubic meters) of soil were removed. The mines were supplied by eight aqueducts extending for nearly 248 miles (400 kilometers) and supplying 16.9 billion cubic quarts (16 million cubic meters) of water a year. Pliny records that the regions of Asturica, Gallaecia, and Lusitania supplied 20,000 pounds of gold per annum.

Under the empire the most important gold and silver mines were controlled by the Roman state. A set of mining regulations dating to the second century CE came from the district of Vipasca, near Aljustrel, in Portugal. The copper and silver mines were controlled by an imperial procurator, and mining concessions were leased out to companies, or *societates publicani*.

Roman Theories on Farming

Marcus Porcius Cato and Marcus Terentius Varro were Roman aristocrats who wrote manuals on agriculture for other members of the nobility in the first century CE. Varro dedicated his manual to his wife, who had just bought a farm. The treatises of Cato and Varro gave readers practical advice: how large an estate to buy, how many olive trees to plant, how many slaves to buy, and the like. Cato and Varro treated soil science at length and were aware that soils must be fertilized to retain their fertility. They may have assumed that they need not belabor every point because their audience was comprised of experienced farmers. Perhaps for this reason the authors did not discuss the use of agricultural technology in detail. One might characterize their treatment of agriculture as prescientific.

View of the mines at Las Médulas, Spain. (Benedict Lowe)

Cato and Varro understood that farmers could not practice monoculture year after year without reducing soil fertility. Varro recommended that some land be left fallow every other year to restore its fertility, though he also recommended that other land be cropped continuously. Both Cato and Varro advised farmers to manure their soil to restore its fertility. Varro ranked dung from thrushes and crows the best, though he did not propose how a farmer might get bird dung in quantity. Varro ranked human excrement second; dung from goats, sheep, and donkeys third; and horse manure fourth. Curiously, he omitted pig manure though he opined that every farm should have pigs. Cato rated pig dung and urine excellent for spreading around pomegranate trees. He recommended that farmers allot half their manure for forage crops, one-fourth around olive trees, and one-fourth for rangeland. This allotment left nothing for the vineyard, though Cato nonetheless urged that farmers spread manure around grape vines. Both Cato and Varro recommended the planting of legumes to restore soil fertility. The advice was prescient, for scientists now know that legumes fix nitrogen in the soil. Interestingly, Cato was unaware that chickpeas are legumes and cautioned against planting them.

Cato and Varro took pains to ensure that farmers planted the right crop in the right soil. Their advice was a foundation for the science of agronomy. Without detailing his thoughts, Cato recommended that farmers plant the crop variety best for a region. He upheld heavy soils as best for grain and heavy warm soils as best for olives. Tantalizingly he recommended the planting of hybrids, though he gave no indication of what he understood the term to mean. In any case the Romans never seem to have appreciated the value of hybrid vigor in the breeding of many crops. Cato and Varro may not have known that plants have male and female parts, a fundamental insight for the breeding of crops. Varro recommended the planting of grain on flat land, spelt on wet soils, barley on dry soils, wheat on intermediate soils, and grape vines on hillsides. Varro advised farmers to save seed from the largest, most vigorous plants for planting next season. Farmers practiced this method of seed selection into the twentieth century.

➤ ROMAN PLOW

Among the oldest agricultural implements, the plow was the principal technology for breaking the soil in preparation for the planting of seeds. The Roman plow differed little from its Near Eastern predecessor. The Roman plow had a long horizontal beam that rode on top of or slightly below the soil surface. At the front of the beam was the plowshare, which broke the soil. The Romans understood that a wooden plowshare wore quickly, so they fastened sheets of iron onto the front of the beam. Attached to the beam was a curved length of wood to which a farmer yoked draft animals. Varro recommended oxen as draft animals on heavy soils and donkeys on light soils. He counseled farmers to plow a field twice in spring, with the second plowing at a right angle to the first. Farmers then broadcast seed and plowed a third time to cover seeds with soil. Cato likewise urged farmers to plow the soil in spring, working the driest ground first and the heaviest, wettest land last.

—Christopher Cumo

Cato and Varro lived at a time when slavery was common. Neither questioned that farm owners should use slaves to do the work. Varro cautioned against using slaves on swampland or on other lands where diseases were prevalent. Apparently the investment in slaves was too great to expose them to premature death. Cato and Varro described the routine of work in detail, and both advised farmers against allowing their slaves to be idle. The abundance of slaves and of hired hands may have led farmers to de-emphasize labor-saving machinery. For example, few farmers adopted the vallus, a mechanical harvester. Instead, as farmers had for centuries, Romans harvested grain with a sickle.

Cato and Varro were prolific writers, yet few of their works are extant. The fact that their manuals of agriculture have survived evinces their quality and the desire of humans for practical knowledge.

Drawloom Technology in China

The first documented drawlooms date from about 400 BCE in China, which is the Chu period. Before the invention of the drawloom, the simpler treadle loom was used for weaving textiles. It required a single person and was capable of only basic designs. The drawloom was a more complex affair, requiring two people to operate, but it was capable of weaving complex patterns. Repeating patterns, known as repeats, could be set in the arrangement of the frame, thereby enabling the operators to efficiently and accurately manufacture cloth with intricate designs.

ANCIENT CHINESE DRAWLOOMS AND THE ORIGINS OF COMPUTERS

It is possible to trace the origins of modern computers to ancient Chinese drawloom technology. French inventor Joseph Marie Jacquard (1752–1834) saw the potential in improving the capabilities of the drawloom by doing away with treadles and controlling the yarns with a system of punch cards and pins. These punch cards and pins controlled the positions of the warp yarns with such finesse that pictorial patterns were made possible. In turn, the British inventor Charles Babbage took Jacquard's idea and used punch cards to program one of his mechanical computers, known as an analytical engine. The concept of preset programs for controlling computers and other machines is the basis of modern technology. The embryonic idea of computation can therefore be traced back to the Chinese drawloom, invented more than 2.5 millennia ago. In essence it is all about asking a machine to think for itself but in a controlled manner.

—Gerard Cheshire

Mechanically the drawloom is so-named because it has a frame attached above, known as the drawboy, that functions as a mechanical boy, drawing or lifting the appropriate heddles to achieve the desired arrangement in the weave.

Each heddle, or heald, has a loop through which a warp yarn passes. The raising or lowering of a heddle therefore causes its yarn to warp upward or downward in a corresponding way. Accordingly, the weft yarn rides above or below the warp yarn so that the pattern is built up with each pass of the shuttle. The actions of the heddles are controlled by foot pedals called treadles, which are attached to the drawboy via cords.

The invention of the drawloom seems to have coincided with the burgeoning silk industry in China, and its addition resulted in highly sophisticated and ornate fabrics fit for kings, as it was usually only the Chinese rulers and aristocracy who could afford such fine cloth. This was during a period in Chinese history when the Chu kingdom was prevalent: 722–221 BCE.

Some scholars question the Chinese origin of the drawloom, suggesting that it was invented in Asia Minor. They point to the technique shown in ancient samples of cloth, as opposed to any archaeological evidence. As with many distant historical events, it is likely that no one will ever know for sure.

Whatever the true origin of the drawloom, its introduction is now regarded as a seminal event in textiles. It has been compared with the invention of movable type in printing because of its impact on the weaving industry.

Apart from increasing the intricacy of designs, the drawloom also made the process more efficient and improved the rate of production. Once the drawloom was set up, the operators could run through a sequence of settings and churn cloth out at an industrial pace. In turn, this meant that surplus cloth and carpets became available for trade with other regions.

In effect, the drawloom was the first programmable machine. That is to say, the presets in the drawboy were a form of primitive programming, as the treadle operator knew that depressing a particular treadle would result in a reliable outcome. In fact, one might even say that the drawloom was the first mechanical com-

puter. The French inventor Joseph Marie Jacquard refined the concept of the drawloom in the early nineteenth century by introducing punch cards and pins that controlled the positions of the warp yarns with such finesse that pictorial patterns were made possible.

Development of the Karez System

In the arid climate of much of central Asia and Iran, agriculture can often be difficult. Although water from streams and melting snow allows large settlements to be possible in the highlands, in lower areas without irrigation this can be nearly impossible. However, early agriculturalists developed an effective albeit labor-intensive system to allow agriculture to flourish. This is known as *karez* in Persian and *qanat* in Arabic and is one of the most impressive engineering feats of the ancient world.

The system appears during the first millennium BCE and evolved from simple irrigation channels that one would find anywhere. However, in the arid climate of central Asia and Iran, these channels could lose significant amounts of water through evaporation, thus necessitating a more efficient system.

The karez works in a simple but ingenious manner. To avoid water loss via evaporation, the water travels from its source via man-made underground channels. These channels are roughly 6 feet (2 meters) high, although the water is rarely more than 3 feet (1 meter) deep. Vertical shafts are sunk in order to access the water via a well. These shafts are wide in diameter, as they

➤ BUILDING THE KAREZ

Who built the *karez* networks or irrigation channels? Soviet scholars studying those found in central Asia concluded that it was slave labor. Scholars have now dismissed that conclusion because it fit too neatly into a Marxist framework. It seems more likely that villagers built it to fit their needs. Indeed, in pre-Islamic central Asia there is evidence that a school of irrigation engineering existed. Indeed, considering the feat of extending these channels up to a couple of miles, the skill of professional engineers and mathematicians was necessary. Thus, the village that would benefit from the irrigation and had the most at stake would do the labor but hire an engineer to help in the planning and construction.

—Timothy May

also serve to ventilate the water channels and as access points for maintenance. By descending the shaft, workers can repair shafts, clear debris, and generally ensure that the karez functions as it should. At times, the water must travel in aboveground canals. Again, water loss via evaporation remained a concern, so palm or other trees provided shade for the canal. Reservoirs were also built periodically to store water.

As towns grew around natural oases, the karez system functioned to bring additional water. This often required the karez to bring water more than a mile from its source. In some areas more than 300 wells have been found that tap into the subsoil channels. From an aerial view, you can follow the path of the channel by well holes.

The use of the karez turned marginal agricultural areas into fertile lands. It also allowed for a larger population. During the Han dynasty of China (206 BCE–220 CE), the karez allowed them to establish garrisons in the Turfan basin, located in present-day Xinjiang, in order to gain access to horses and trade with the nomads and oasis towns of central Asia. Indeed, it is thought that the Chinese introduced karez irrigation to the Turfan basin, although it developed in Iran and west-central Asia independently.

Development of Felt Manufacturing in Central Asia

Although most sedentary cultures developed textiles from thread made from vegetable fibers (cotton or flax) or animal products (wool, silk), in central Asia wool was the primary textile. The nomadic cultures further separated themselves from the sedentary cultures by using woolen products but not in the form of a thread. This strong and durable nonwoven fabric became an integral part of central Asian clothing and manufacturing. As sheep were a central element for all pastoral nomads across central Asia, felt production was common among all nomads. While the first recorded mention of felt products dates to around 500 BCE, it was certainly used before then, as Greek, Chinese, and Persian observers noted that the nomads used it to construct their homes.

Scythian horseman with cloak and mustache, detail of a Scythian felt cloth from a frozen tomb in the Paryryk Valley, Altai Mountains, fifth-fourth century BCE. (Erich Lessing/Art Resource, NY)

The earliest examples of felt were found in Scythian tombs in the Altai Mountains. Used for saddle blankets and coverings, wool was also used as appliqués on clothing and in housing. Indeed, felt was a fundamental element of housing and also covered the yurts of all nomads. Known for its insulating properties, it was critical for surviving the cold winters of the steppe. Thus, during extreme cold another layer could be added quite easily.

Of course, felt was used for other purposes as well. Archaeological finds in Mongolia and Siberia have also yielded felt rugs and linings for boots. Indeed, even Chinese observers, though often contemptuous of the nomads and their rough ways, remarked that felt clothing was better than silk in the steppe due to its warmth and also its ability to protect against cuts from brambles and thorns in the wilderness. Indeed, while the nomads enjoyed silk garments, they often lined their robes with felt for insulation while keeping the silk on the outside for ornamentation. Indeed, Chinese sources note that the Xion-

➤ FELT MANUFACTURING

Felt is made from taking wool and crushing it together. As wool has microscopic scales, when it is pounded the individual strands rub together, and the resulting abrasion cause the scales to interlock and form a compact layer. Typically the wool is carded or separated. Then layers are placed on top of each other with the strands running in alternating directions. After enough layers are in place, and this varies depending on the purpose, the wool is rolled up and pounded. This pounding process is conducted with wooden

staves, other utensils, or with the body. With the body, the person picks up the wool and places it on a surface such as the ground, a board, or a wagon and then forcefully crushes it with the chest. Then the wool is moved and the process repeated. The techniques for felt manufacturing were based on convenience and local folkways; felt manufacture required little technology and any tools needed could be created with materials at hand.

—Timothy May

gnu tribes and other groups in Mongolia used it as light armor, often reinforced with strips of leather or of metal sewn onto it. It is unclear if the Scythians or other tribes in the Pontic and Caspian steppes used it as armor, although writers such as Herodotus may not have understood that felt as clothing might have also had a defensive purpose. Otherwise, the material's function as clothing, shelter, and other utilitarian purposes appears to have been similar across the steppe lands of Eurasia.

Olmec Stone Moving Technology

Colossal stone monuments are the most characteristic feature of the Olmec culture from the Gulf Coast of Mexico. Sculptures include giant portrait heads, which could measure up to 9 feet (2.7 meters); platform thrones, or altars; and stele (upright stone slabs), typically decorated with low-relief carving. These large sculptures were an integral part of the architectural design of ceremonial centers, such as San Lorenzo and La Venta.

The basalt, a type of volcanic rock employed to create these sculptures, however, originated quite far from the sites of their final and current location. Microscopic analysis revealed that the main source can be traced to Cerro Cintepec, an extinct volcano on the Tuxtla Mountains roughly 37 miles (60 kilometers) away from San Lorenzo and La Venta. Boulders can be found on the surface on the volcano's slopes and do not need any major cutting prior to transportation.

Large semiworked boulders, some weighing up to 40 tons (roughly 89,000 pounds), were

transported from Cerro Cintepec to the final destination using both land and fluvial routes. The main quarry is almost 30 miles (48 kilometers) away from the nearest navigable river, while both San Lorenzo and La Venta lie at the banks of major waterways. Speculations on the possible routes utilized by the ancient Olmecs (there are no written accounts from this early period) are based on aerial photographs and topographic maps as well as comparative analysis with stone-moving technologies among other early civilizations (e.g., ancient Egypt and Assyria and prehistoric Easter Island).

First, land transportation was carried out with sledges pulled by sheer manpower, given the lack of beasts of burden and wheel technology in ancient Mesoamerica. Ramps were used to load the boulders on the sledge. The stone boulder needed to be flattened on one side in order to rest firmly on the wooden crossing beams of the sledge. The employment of natural substances to reduce friction on the ground would have been essential for reducing the number of men necessary to carry out the job, although there is no direct evidence to indicate what agent may have been used. It has been calculated that roughly 1,000 men would have been needed to pull overland an average boulder from the main quarry to the riverbanks. If sleepers were employed, additional workers would have been needed to move the sleepers from beneath the sledge to the front. Coordinating operations such as replacing fatigued laborers and providing food would have also required additional workers.

At a calculated speed of roughly 236 inches (600 centimeters) per hour, it would have taken 135 days to carry the boulders from the quarry at Cerro Cintepec to the main river at Coatzacoalcos.

Water transportation was much easier. The large boulders were hauled on log rafts, measuring approximately 35 feet (10.7 meters) long, 20 feet (6.1 meters) wide, and 4.2 feet (1.3 meters) deep. Canoes may also have been employed. Most likely, multiple canoes were joined together by crossing beams, which served as the resting surface for dragged boulders. From the loading point at the Coatzacoalcos River, it would have taken four days to reach the site of San Lorenzo and about six days to reach La Venta.

Olmec stone-moving technology was an important aspect of socioeconomic relations in early Mesoamerica. A large portion of the local population was involved in the quarrying, dragging, and loading of the boulders from Cerro Cintepec to the major ceremonial sites, where they served their final functions as historical monuments and ritual altars. Although knowledge on the specific technological tools remains speculative, archaeologists agree that organizing this operation would have required a high degree of social complexity.

Andean Water Systems

The South American Andes region is home to great biogeographic diversity, including rain forest, high arid plains (also called *puna*, or Andean Altiplano), and coastal desert valleys along the Pacific. This region has been under continuous agricultural cultivation by humans in its variety of ecosystems for several thousand years. After the Iberian conquest in the sixteenth century, highland agricultural techniques of indigenous peoples of the Incan empire were chronicled to some extent by Spanish observers. For this reason, the Incan empire, which existed for only a short time in its unified form before Pizarro's conquest of 1532, is most frequently associated in both public and scholarly perceptions with notions of pre-Columbian Andean settlement. Perhaps most famous among complex highland

Andean settlements are the terraced agricultural and water systems of Machu Picchu, an Incan city that was never discovered by the Spanish conquerors but instead was first described for academic audiences by an American team of archaeologists in the early twentieth century.

In the later twentieth century, thanks to increased archaeological interest and new methods of data collection, for example, through archaeobotany and palynology (analysis of pollen from agricultural and other plant products trapped in soil sediments), a new debate has emerged among anthropologists and geographers about the earliest origins of agricultural settlement in the Andes. At present, there is no scholarly consensus on the earliest date of intensive agriculture in the Andes. Archaeologists of this region and period refer to broad cultural eras of settlement known as the Initial Ceramic period (1800–900 BCE), the Early Horizon (900–200 BCE), and the Early Intermediate period (EIP; approximately 300 BCE–600 CE, depending on the source of estimation). The earliest possible dates for irrigated agriculture in the Andes region are variously estimated from 4000 BCE to 1800 BCE, toward the end of the Pre-Ceramic period.

Under arid conditions irrigation becomes necessary for agricultural production, and the resulting landscape patterns and structures of irrigation are sought by archaeologists searching for ancient and abandoned sites of settlement. In the Andes region, with the various types of arid ecosystems found there, intensive agriculture requires some level of human intervention by diverting water from natural pathways (rivers, streams, rainfall, lakes, or springs) to the desired site of agricultural settlement via constructed canals, dikes, ditches, dams, or terraces. Irrigated agriculture is important either seasonally or year-round, depending on levels of rainfall and moisture.

There are several distinct types of arid zones for irrigated agriculture in the Andes, following changes in altitude, temperature, topography, soil, and moisture. Archaeological investigations have identified the earliest small-scale irrigation works in coastal valleys (approximately 3000–4000 BCE) and other early sites of irrigation (possibly 2400–3000 BCE) in the mountain valley of La Galgada. The Moche Valley along the northern Pacific coast, home to the Mochica set-

tlement during the EIP, is considered to be a site of impressive architecture, canal building, and water distribution, though most extensive evidence for these networks of canals comes from subsequent periods on the same site.

Recently, anthropologists of environment and agriculture have tried to integrate the ancient past and present of Andean ecosystems into a more continuous framework, relying on dynamic environmental factors and enduring crop systems to define a range of indigenous technologies and livelihoods from the first origins of regional agriculture up until the present. By attributing indigenous heritage to the sophisticated engineering projects of the pre-Columbian past, advocates see an opportunity to reinvest disempowered indigenous peoples with the respect and heritage of expertise that was denied to them in the conquest of the Americas and subsequently denied again by Eurocentric models of expertise, large-scale technical improvement projects, and modernization programs.

In the 1980s a research collaboration between structural engineers and field archaeologists of this region concluded that the role of dynamic river systems, geological tectonic movements, and cycles of decadal or centennial flooding (tied to the El Niño climatic phenomenon) had contributed to structural instability,

abandonment, and then reconstruction of extensive Moche Valley canal works of the Chimú state, founded after the EIP. Since the researchers concluded that these forces of environmental change are continuous in the Andean context, there are further reasons for water systems engineers of the present to pay attention to an archaeological record of adaptation to dynamic environments.

■ Introduction: Monumental Wonders of the Ancient World, 1000 BCE–300 CE

Six of the seven wonders of the ancient world were constructed between 1000 BCE and 300 CE. Only the Great Pyramid of Giza was built earlier (and it is the only one still intact), having been constructed during the Fourth Dynasty of Egypt (2613–2494 BCE). That the rest have long since vanished but are still remembered nearly 2,000 years later is a testament to the impact that these wonders had on the ancients. These were not the only wonders that this period had to offer though, as tourists to Italy, China, and Mesoamerica can attest to. The following entries present some of these ancient

architectural marvels, some still standing and some long destroyed, that still captivate our imagination today.

—Kevin M. McGeough

The Seven Wonders of the Ancient World

The concept of the seven wonders of the ancient world was developed from the writings of various Greek philosophers, historians, and geographers who discussed these places amid their

➤ ANTIPATER OF SIDON ON THE SEVEN WONDERS OF THE ANCIENT WORLD

“I have set eyes on the wall of lofty Babylon on which is a road for chariots, and the statue of Zeus by the Alpheus, and the hanging gardens, and the Colossus of the Sun, and the huge labor of the high pyramids, and the vast tomb of Mausolus; but when I saw the house of Artemis that mounted to the clouds, those other marvels lost their brilliancy, and I said, ‘Lo, apart from Olympus, the Sun never looked on aught so grand.’”

Antipater, *Greek Anthology* (IX.58), in William Roger Paton, ed. and trans., *The Greek Anthology* (Cambridge: Harvard University Press, 1917), 31.

travels during the Classical and Hellenistic periods of Greek history. It is primarily through the writings of Antipater of Sidon, Philo of Byzantium, Herodotus, Strabo, and Diodoros Siculus that the concept of the seven wonders of the ancient world developed. Moreover, travel guides written during the early Hellenistic period discussed these wonders, or things to see, as major attractions for Greek travelers wishing to explore the new domains of the successors of Alexander the Great. In an expanded Greek world, the seven wonders of the ancient world provided a set of attractions for Hellenistic civilization to be proud of, as five of these were Greek; the other two were Egyptian and Babylonian.

The Great Pyramid at Giza was constructed between approximately 2584 and 2561 BCE by the ancient Egyptians during the Old Kingdom. It was built for the pharaoh Khufu (Cheops in Greek) and is believed to have stood at approximately 481 feet (147 meters) at the time of its completion. Out of the seven wonders, the Great Pyramid is the only wonder that remains. Greek merchants and travelers would have been well acquainted with this major attraction of the Near East.

The Hanging Gardens of Babylon, built by Chaldean king Nebuchadnezzar II around 600 BCE for his wife Amytis of Media, who supposedly missed the landscape of her native land, is documented by Greek writers Diodorus Siculus and Strabo. Built alongside a palace with elaborate balconies and irrigations systems, the lush gardens were noted for being grandiose and expansive. Given that these were supposedly destroyed by earthquakes in the second century BCE, it is uncertain that the documentation left by these writers can be entirely accurate, given that they were not alive during its actual existence.

The statue of Zeus at Olympia, sculpted by Phidias in approximately 432 BCE inside a temple dedicated to Zeus, stood at an estimated 40 feet (12 meters), occupying the entire width of the temple. Constructed of ivory, gold, and bronze, as it was described by various Greek commentators and travelers, its existence can be verified through these corroborated testimonies. The Temple of Artemis at Ephesus, built for the Greek goddess Artemis, is documented to have taken 120 years to construct, beginning around circa 550 BCE. Roman philosopher Pliny the Elder estimated the size of this temple (converted to modern units of measurement) as 377 feet (115 meters) in length and 180 feet (55 meters) in width. Both of these monuments were later destroyed through plundering and vandalism throughout various wars of antiquity but lasted long enough to be documented by Greek writers.

The Mausoleum at Halicarnassus, built for Persian satrap Mausolus around approximately 351 BCE, stood at an estimated 135 feet (41 meters) and was adorned with finely crafted sculptural reliefs on the exterior. For its size and elaborate decorations, Antipater of Sidon documented it as one of the seven wonders. The Colossus of Rhodes, a giant statue of the Greek god Helios, was built on the Greek island of Rhodes between 292 and 280 and stood at approximately 107 feet (33 meters). It was destroyed by an earthquake circa 226 BCE. The Lighthouse of Alexandria, built between approximately 285 and 247 BCE as a major landmark for the port of the city of Alexandria, was estimated to be between 383 and 440 feet (116 and 135 meters) tall. It was documented to have been seen far out to sea and was later destroyed by earth-

quakes in the tenth and fourteenth centuries. These monuments were well documented by writers and travelers.

Palace at Nineveh

Under the reign of Assyrian king Sennacherib (704–681 BCE), the capital of Assyria was moved to Nineveh from Dur Sharrukin. Upon relocating the new Assyrian political and military center to Nineveh, Sennacherib commissioned the construction of a grand new palace. Known as the “palace without rival,” it was lined with elaborate reliefs and inscriptions to commemorate the king’s accomplishments in battle as well as the power and glory of Assyria. The palace was built on the mound of Kouyunjik, on the southwestern corner, adjacent to the walls of the city of ancient Nineveh. The palace’s rooms were characterized by limestone slabs with inscriptions of scenes of Sennacherib’s heroic deeds. However, when Nineveh was sacked in 612 BCE by an allied force of Babylonians and Medes, Sennacherib’s palace was utterly destroyed, burned, and pillaged by the invaders. It was rediscovered in 1847 by British archaeologist Austin Henry Layard, who was the first to excavate the site.

Layard’s excavation of the “Southwest Palace” (which is how he referred to the “palace without rival”) from 1847 to 1851 led to the discovery of an inner chamber within the structure. In this chamber, the wall reliefs described in cuneiform script Sennacherib’s siege of the Judean city of Lachish. This event was corroborated in the second book of Kings in the Bible, thereby confirming the historical accuracy of the event in question. Further finds from the palace also confirmed other events that had previously been documented only in the Old Testament, such as the Assyrian siege of Jerusalem. George Smith, an Assyriologist who worked at the British Museum (where the treasures of Nineveh were brought after excavation), discovered among the

➤ SIR AUSTEN HENRY LAYARD (1817–1894)

British archaeologist Sir Austen Henry Layard, the excavator of Nineveh (particularly the site of Kuyunjik) and Nimrud (near Mosul) in what was the ancient civilization of Assyria in Mesopotamia, is notable for his multiple discoveries and the popularization of Assyrian archaeology in Victorian Britain. He was born in Paris and educated in Italy, England, and Switzerland, and his travels abroad took him to the Ottoman empire, where under the auspices of the British Foreign Ministry and the British Museum he undertook various excavations in Ottoman Mesopotamia. Among his important findings were the palaces of Assyrian kings Ashurbanipal II, Shalmaneser II, and Tiglath-Pilester. Layard is best known for his discovery of the ancient Assyrian capital of Nineveh (1847), on the other side of the Tigris River from Mosul, where he discovered the ancient palace of Sennacherib (1849). Layard also found extensive collections of cuneiform tablets that allowed scholars to decipher aspects of Assyrian and Babylonian history and culture. His discoveries in Nineveh and his subsequent publications, most notably his *Discoveries in the Ruins of Nineveh and Babylon* (1853), popularized his findings among the educated British public. Moreover, his collections of Assyrian archaeological findings in the British Museum promoted Mesopotamian archaeology and history within British society, sparking further interest in the study of Near Eastern civilizations.

—*Abraham O. Mendoza*

palace’s tablet archive an account of a flood that was remarkably similar to the story of the biblical deluge. He was then sent to the actual site to find more cuneiform tablets.

Many of the features that characterize Sennacherib’s palace are based on other Assyrian palaces built by his forbearers, albeit to a grander and more elaborate extent. Among these shared traditions of palace architecture in Assyria are their distinctive architectural style, the layout of the decorations, and the subject matter of the various elements that make up central royal chambers and the myriad rooms. The palace had a long, wide room for royal receptions, with multiple doors to connect this chamber with a considerably large outer court area and adjacent terraces.

The royal throne was positioned in the southeast end of this chamber flanked by a wall that faced a staircase on the opposite end. The layout of decorations and monumental art in the palace was characterized by the prevalence of stone orthostats (upright stone slabs) carved with inscriptions and artwork, which narrated important events in Assyrian history. Doorways were adorned by adjacent stone statues of deities or Assyrian kings. The subjects of these various decorative elements in the palace commemorated significant events related to the reign of the current king, typically battles and other accomplishments related to warfare. The assumed purpose of these royal chambers was to captivate those received by the king through the sheer magnitude of the artwork, attesting to the wealth and power of the sovereign but also to draw reverence to the Assyrian state.

Parthenon in Athens

The Parthenon served not only as a religious temple but also as a civic symbol representing the greatness and glory of ancient Athens. The construction of temples in ancient Greece, which were built beginning in the eighth century BCE, coincided with the establishment of the Greek city-state. After the end of the Persian Wars and the establishment of Athens as a major center of power in Greece, the Parthenon was built on the site of an older temple for Athena, the Greek goddess for whom the city was named. The goal of the building project was to exemplify the greatness of the city and its patron goddess 30 years after Athens' pivotal role in the defeat of the Persians. Set atop the Acropolis, a high flat promontory in Athens, the Parthenon, one of a series of

structures, was originally built in 447 BCE and completed in 432/431 BCE. It still stands today, despite centuries of decay and weathering, as a symbol of the greatness and grandeur of ancient Athens.

The first attempt to build a major temple dedicated to Athena occurred after the Battle of Marathon in 490 BCE, which suggests that it was built to give Athena thanks for this great victory. However, in a subsequent Persian invasion of Athens, this temple on the Acropolis was razed to the ground as Persian forces set about destroying Athens in 480 BCE. That year a major Athenian naval victory at the Bay of Salamis destroyed the Persian fleet. A subsequent land victory by a Spartan-led army the following year ousted the Persians from Greece and ended the threat of foreign domination. During this time, Athens had formed the Delian League, a powerful alliance of coastal city-states and islands in which each member contributed to a common treasury kept at the island of Delos. Athens held the dominating role, which allowed it to seize the assets of the treasury to use for major construction projects, among these a new temple to Athena.

In the mid-fifth century BCE the Athenian Acropolis became the de facto seat of the Delian League, which was now well established as an Athenian empire. Thirty years after the defeat of the Persians, Athenian statesman Pericles initiated an ambitious building project lasting throughout most of the century, with the support of the Athenians. Four major buildings were constructed on the Acropolis in Athens, among them the Parthenon, the Propylaea, the Erechtheion, and the temple of Athena Nike. These structures were meant to promote civic pride, create employment, and give thanks to Athena for their victories. The Parthenon itself was built under supervision of the sculptor Phidias. The main architect Ictinus began construction in 447 BCE. While most of the construction of the Parthenon was completed by 432, the work on the decorations lasted for another year. Most of the expenses incurred were from extracting and shipping marble from a local quarry 9 miles (15 kilometers) away.

The Parthenon was built on the same site and on the actual foundations of the building destroyed by the Persians. Most of what could be

THE MANY LIVES OF THE PARTHENON

The Parthenon served as a Greek temple to Athena throughout most of its trajectory under the ancient Greeks. However, it was looted by the Romans in the fifth century CE, with the great statue of Athena transported to Constantinople. Afterward, the temple served as a Christian Church and became a center for pilgrimage for centuries, known throughout the Orthodox world as the Temple of Theotokos (Mother of God) Atheniotissa. It briefly served as a Catholic church after Athens was taken in the Fourth Crusade in 1204. After Athens was conquered by the Ottoman Turks in

1456, it served as a mosque, with the Turks adding a minaret to the structure. In 1687, in a minor war between the Ottomans and Venice, the Ottomans used the building as a gunpowder magazine, and it was blown up during battle, causing significant damage to the structure. The Venetians, and later the British, looted most of the remaining internal structures. Centuries of vandalism, decay, and weathering have taken its toll on the structure, which still stands today nonetheless as a testament to the grandeur of ancient Athens.

—Abraham O. Mendoza

salvaged was reused in the construction of the newer structure. Ictinus designed the new building on a different scale than the prior structure, attaching extra sets of marble Doric columns. Instead of the typical six-column width characteristic of Doric temples, the new Parthenon was eight columns wide. The interior of the Parthenon consisted of two main chambers. The larger of the two, known as the Hekatompedon, housed a giant ivory and gold statue of Athena. The other room, known as the Parthenon (from which the building takes its name), served as a vault for the Athenian treasury. The Parthenon served multiple functions for the ancient Athenians: a temple to Athena, a victory monument to the defeat of the Persians, a treasury, and a war memorial to commemorate the Athenian dead.

Second Temple in Jerusalem

Initial construction of the Second Temple in Jerusalem was begun in 535 BCE and completed by 516 BCE. The First Temple (also known as Sol-

omon's Temple) had been destroyed at the hands of the Chaldeans as the Kingdom of Judea fell to the Babylonian empire of Nebuchadnezzar in 586 BCE. Subsequently, Jewish elites were taken into exile as captives of the Babylonians (Chaldeans) in an episode known as the Babylonian Captivity (ca. 586–537 BCE).

The Second Temple was built after the Babylonian Captivity and authorized by Cyrus the Great of Persia, who defeated Babylon in 537 BCE. Upon the release of Judeans from Babylon following Cyrus the Great's defeat of the Chaldeans, Cyrus authorized the reconstruction of the Temple of Jerusalem. Among the many concerns of the newly freed Hebrews was the reconstruction of the Temple to give homage to their deity and reassert their traditional religious practices in their homeland. The Temple was completed in 515, almost 20 years after the end of the Babylonian Captivity, and consecrated in 516 BCE. According to Scripture, the Second Temple lacked many elements of the First Temple that had been seized in prior invasions at the hands of the Assyrians and the Babylonians, such as the Ark of the Covenant, Aaron's rod, and the Ten Commandments. However, many of the vessels of gold that had been taken by the Babylonians were restored by the Persians in their attempts to conciliate the Hebrews with foreign rule.

The Second Temple entered a new phase nearly half a millennia later under the rule of the notorious Hebrew leader King Herod the Great, a client-king of the Roman empire. Some historians suggest that this renovation project was

MODEL OF THE SECOND TEMPLE

(Hanan/Sachar/Corbis)

A model of the Second Temple, built in 1966, is currently in the Israel Museum in Jerusalem (formerly housed in the Holy Land Hotel). It is a replica of Herod's expansion of the Temple Mount complex, which was destroyed by the Romans in 70 CE. It is part of a larger model of the city of Jerusalem from the era of the Second Temple. From this model's depiction, visitors can see the Main Hall of the Temple (the Hechal), containing the Holy of Holies, and the outer Altar and Inner Sanctuary.

—Abraham O. Mendoza

priesthood, and much of the Hebrew population were skeptical of Herod's scheme.

This led to Herod's need to quarry all the stones required for the project before the destruction of the earlier Second Temple structure could be initiated. Herod and the Jewish religious authorities also had to make an agreement that the sacrificial rituals, known collectively as the *korbanot*, were to be continued during the entire process of construction. Furthermore, the Cohanim would be responsible for supervising the construction of the project. Estimates about how long the construction process lasted range from three years to half a century. Ultimately, the Romans destroyed Jerusalem and razed the Second Temple on August 4, 70 CE, in order to quash the Jewish Revolt, which had erupted in 66 CE. The temple's destruction at the hands of the Romans as they razed Jerusalem to the ground took place 90 years after the initial announcement of its construction was made.

The Roman Colosseum

The Colosseum, or Flavian Amphitheatre, was originally planned by the emperor Vespasian to help win over the Roman populace to the rule of the new Flavian dynasty. Under the previous emperor, Nero, the site of the Colosseum had been occupied by an artificial lake, part of the extensive parklands surrounding Nero's palace in the heart of Rome, the Domus Aurea (Golden House). The Colosseum took its nickname from the colossal statue of Nero that once stood beside the lake. Many Romans were upset that Nero had occupied so much land in the heart of the city for his own amusement, and so it was a political masterstroke when Vespasian, upon becoming emperor in 69 CE, decided to convert part of the former imperial estate to a public entertainment venue. The lake was drained, and

undertaken to bring wealth into Jerusalem from Jewish Diaspora religious pilgrimages and also to reinforce Herod's reputation in the region following a period of persecutions of Jews under Herod's command. Herod's Temple in Jerusalem was a grandiose expansion of the Temple Mount complex. It included the construction of a completely new and much larger Jewish Temple than the one completed in 515 BCE. The older Temple, which had been built by Jewish leader Zerubbabel nearly half a millennium before, was a small structure. Despite frequent renovations in prior periods, most significantly under the rebellious Maccabees, it was in a deplorable and decayed state prior to Herod's improvements. According to historical records and Scripture, around 20 BCE King Herod announced that the old Temple would be demolished and replaced with a new and much larger structure. The Cohanim, which was the existing high Jewish

construction began on the Colosseum early in his reign. Many of the necessary construction funds came from booty that was captured during the Roman sack of Jerusalem in 70 CE. Amid much fanfare, the inaugural games in the recently completed Colosseum were staged by Vespasian's son Titus in 80 CE.

Like other Roman amphitheaters, the Colosseum was elliptical in shape: the building's exterior measurements were 616 by 511 feet (188 by 156 meters). A ring of seating (*cavea*) surrounding the arena floor, 167 feet (51 meters) wide and 159 feet (48.5 meters) high, is estimated to have held some 50,000 spectators. Four tiers of concentric passages underneath the *cavea* as well as radial stairways that divided the seating into wedge-shaped sections (*cunei*) allowed spectators to quickly circulate throughout the various levels of the building to find their seats. In addition, spectators were directed to one of over 70 numbered entrance arches by their tickets, which ensured that they entered the Colosseum as close to their seats as possible. The seating was also divided horizontally into six tiers: the lowest tiers were reserved for the Roman elite, while the highest were open to women and commoners.

A variety of materials were used in the Colosseum's construction. A massive ring of concrete, some 164 feet (50 meters) wide by 39 feet (12 meters) deep, was sunk into the former bed of Nero's lake to support the structure above. Travertine piers on top of the concrete foundation further supported the building's enormous weight. In addition, the highest tier of seating was made out of wood rather than marble so as to minimize the weight load on the structure.

A number of other architectural features ensured both the comfort of spectators and the orderly staging of spectacles in the Colosseum. Still visible today on the arched travertine facade of the Colosseum are the stone corbels that once helped support the *velarium*, the awning that could be extended to provide shade for spectators on particularly hot days. A substructure later added to the Colosseum contained animals cages and various spectacle props that could be raised to the arena floor whenever necessary.

—Christopher Epplett

➤ MARTIAL ON THE COLOSSEUM

The contemporary poet Martial gives us a good impression of the wonder caused in Rome by the opening of the Colosseum:

“Let barbarous Memphis speak no more of the wonder of the pyramids, nor Assyrian toil boast of Babylon; nor let the soft Ionians be extolled for Trivia's temple [temple of Diana at Ephesus]; let the altar of many horns say naught of Delos; nor let the Carians exalt to the skies with extravagant praises the Mausoleum poised in empty air. All labor yields to Caesar's Amphitheater. Fame shall tell of one work in lieu of all.”

—Christopher Epplett

Roman Pantheon

The Pantheon (“Temple of all the gods”) was originally built in Rome during the reign of Augustus (31 BCE–14 CE). The construction was entrusted to the emperor's right-hand man, Agrippa, who dedicated the Pantheon in 27 BCE as part of his monumental building program in the Campus Martius. Despite the name of the Pantheon, its primary purpose was to honor the emperor's family, the Julian clan.

Unfortunately, in part due to later rebuilding, the original design of the Pantheon is not absolutely clear. The original Pantheon appears

The Pantheon in Rome, Italy. (Rob Meehan)

➤ GIVING CREDIT WHERE CREDIT IS DUE

Hadrian, who was a very active builder throughout the Roman empire during his reign, was careful to give credit to the original builders of structures he restored. A clear example of this is seen in the Pantheon. As a mark of respect to his predecessor, Hadrian was careful to include the building's original dedicatory inscription in the rebuilt Pantheon, an inscription that is still clearly visible on its facade: "M AGRIPPA L F COS TERTIVM FECIT" (Marcus Agrippa, son of Lucius, consul for the third time, constructed [this building]).

—Christopher Epplett

to have been a rectangular temple some 65 by 144 feet (20 by 44 meters) in size, with its main entrance on the south side. Somewhat unusually, the *cella* (main chamber) of the temple was not aligned with the porch but instead was situated perpendicular to it. Like many other Augustan monuments, the original Pantheon was built at least partly in marble. In addition, as Pliny the Elder informs us, the Pantheon was decorated with Caryatid columns (carved in the form of women) sculpted by Diogenes of Athens, a classicizing element that it shared with the Forum of Augustus.

The original Pantheon was one of many buildings in Rome destroyed by fire in 80 CE. The emperor Domitian subsequently rebuilt the

Pantheon, but the rebuilt structure was itself destroyed by another fire in 110 CE. It was therefore left to Hadrian to once more rebuild the Pantheon after becoming emperor in 117 CE. Brick stamps on the Pantheon not only indicate that construction began the following year but also that the Hadrianic reconstruction obliterated virtually all remaining traces of earlier building on the site.

Hadrian's Pantheon, largely preserved because of its conversion to a church in 608 CE, is a distinct departure, in terms of design, from its previous manifestations. The front of the structure consists of a rather typical eight-columned porch and pediment; the design of the rest of the structure, however, is anything but conventional. The interior of the Pantheon, in its most basic terms, consists of a cylinder topped by a dome. The interior diameter of the cylinder (141.7 feet, or 43.2 meters) is equal to the interior height of the building at the top of the dome. A massive concrete foundation ring, some 14.7 feet (4.5 meters) deep and 33.7 feet (10.3 meters) thick, along with the walls 19.6 feet (6 meters) thick of the cylinder above, supports the weight of the dome. Further stability is also ensured by the fact that the concrete mixture used for the dome is substantially lighter than that employed for the cylinder and foundation.

Despite the bulk of the Pantheon's structure, it is anything but oppressive to anyone entering the interior. A number of optical effects ensure that the visitor is given the impression of space and openness. A large *oculus* (round opening) some 30 feet (9 meters) wide, situated at the top of the dome, provides light to the Pantheon's interior. In addition, architectural effects such as the coffered panels built into the interior of the dome as well as a series of recesses built into the base of the cylinder break up the potential monotony of the building's interior.

The Earlier “Great Wall” of China

The Great Wall of China that still stands today was not the first “great wall” to be built in China. During the Warring States period (481–221 BCE) when warfare was endemic, defense walls were built to keep out invaders, both predatory neighbors and alien nomads. Most regional states, particularly those located in proximity to the steppe lands such as the Zhao, Yan, and Qin, all built their own walls separately. After the Shihuangdi of Qin unified the country in 221 BCE, the internal defense walls fell into disuse, but the northern nomads continued to present a tangible threat to the agricultural community in the south. Thus, the Shihuangdi strengthened the defense walls that the regional states built previously and connected them together as one structure. As the threats from

the north persisted, the Han (206 BCE–220 CE) rulers followed the Shihuangdi’s strategy, building on the wall and using it as a defense line against the nomads through much of the Han era. The wall thus becomes known as the Great Wall.

The Great Wall was a massive engineering feat. It started in Liantao from the northwest in present-day Gansu, cut its way across various landscapes including plains and mountains, and stretched to Liaoting in the northeast. The total length of the wall during the Han period was over 10,000 *li* (1 *li* is about 0.3 miles or 0.5 kilometers). It thus acquires the name of Wanli Changcheng, or the “Ten-thousand-li-long Wall.” Wood, rocks, and bricks were all used as building materials, but the bulk of the wall was made out of earth, which was tamped and hardened. It stood about 65 feet (20 meters) high, making it harder for the horseback-riding nomads to cross; in some parts the top of the wall is 26 feet (8 meters) wide, allowing the defending troops to move back and forth. On top of the tall beacons, sentries would start up fires for smoke signals, signaling the approach of the invading nomads from afar.

➤ SCHOLARLY CONTROVERSIES—WAS THE ANCIENT GREAT WALL REALLY GREAT?

Almost every discussion of Qin Shi Huang's reign includes the one accomplishment that seems to typify both the positive and negative aspects of his reign: the Great Wall of China. According to the typical account, Qin Shi Huang completed earlier Zhou wall construction projects by connecting them all up to form the Great Wall, which he built to protect China from the savage and warlike Xiongnu or "Huns" on China's northern border. He may even have punished laborers who did not work hard enough on the project by executing them and having their bodies buried within the Great Wall. When finished, this Great Wall supposedly extended all the way across China, effectively dividing the Chinese civilization on the south from the world of the barbarians, or pastoral nomadic peoples, of the northern steppe lands. There it remained until the present in one state of repair or another, periodically undergoing renovation projects. Today it stands as monumental and artifactual testament to the industry of the Chinese people and the despotic, boundless ambition of Qin Shi Huang. It is such a magnificent structure that it is the only man-made object on the earth that can be seen from orbit or, by some accounts, the moon.

All of this makes tantalizing copy for travel brochures and grist for the publishing mills that endlessly crank out glossy, coffee-table picture books about China. There is, however, one major problem with this standard and sensationalized description of the Great Wall: according to the historian Arthur Waldron it is wrong in its entirety.

Waldron has exploded hoary legends and proven conclusively that much of what we once thought we knew about the Great Wall is pure myth. First of all, the Great Wall of China is not ancient but was built during the Ming dynasty (1368–1644 CE). Many traditionally minded historians of China have long maintained that although the Great Wall as it stands today was last renovated during the Ming, the site of the wall itself goes all the way back to Qin Shi Huang's day. Waldron, however, has shown that there is only the flimsiest of evidence to support this notion. Earlier Chinese dynasties, including the Zhou and the Qin, did in fact build walls, but the locations of these walls were scattered throughout many areas of northern China and never constituted the one continuous and fixed wall that Chinese and foreigners recognized as the Great Wall. He points out that Marco Polo, whose travels during the thirteenth century CE often took him through areas where the Great Wall supposedly existed, never even mentioned it. Waldron maintains that the Great Wall was built for the first time during the Ming and did not exist in any form before that dynasty. Of course, this is not to say that the Great Wall is not magnificent. All Waldron maintains is that the wall is not ancient.

—David Curtis Wright

Bibliography

Waldron, Arthur. *The Great Wall of China: From History to Myth*. Cambridge: Cambridge University Press, 1990.

➤ THE STORY OF MENGJIANG

There are many folktales about the Great Wall, and one story has become the most popular throughout China, the story of Mengjiang. Mengjiang was married to a man who, soon after their marriage, was drafted to work on the wall. Mengjiang was a devoted wife, waiting patiently for her husband to return. When winter approached she made her husband warm clothes and traveled to Shanhaiguan to deliver them. When she arrived she

learned that he had already died of exhaustion and cold. Deeply in grievance, she cried incessantly under the wall until her tears broke open the part of it, revealing her husband's skeleton and the skeletons of many others. Mengjiang took the remains and buried them properly, and having no other family to comfort her, she threw herself into the sea.

—Yi Li and Constance Childs

The building of the Great Wall consumed tremendous resources and incurred high human costs. The Shihuangdi alone is said to have deployed 70,000 people to work on the project, while the entire Chinese population at that time was no more than 30,000. At the peak of construction, perhaps up to 1 million men worked on the wall, not to mention the high labor cost for the continuous maintenance of it. Many of these workers were either criminals or peasants drafted from the village who were obliged to fulfill their duty to the government. The working conditions were harsh and inhumane, with little security and with many laborers dying on the job. Legends that say that the wall was built on the piles of human skeletons are not entirely without grounds.

Despite the great efforts in the building of the Great Wall, over the long history it did not always protect China from the northern nomads. After the Han fell in 220 CE, the Central Plains were overrun and devastated repeatedly by the invading nomads. The Xiongnu, the Xianbei, and Turks, one after another, had crossed the wall and established their presence in China. However, the wall remains symbolic in separating the agricultural and “civilized” Chinese society from the nomadic and “barbarian” society in the north. As the Chinese increasingly believed that they were the center of the world as the Middle Kingdom, the wall worked better in keeping the Chinese people in rather than keeping the “barbarians” out.

The Maya Temple Pyramids of Nakbe

Located in the *bajos* (lowlands) of the northern Petén region of Guatemala, Nakbe was the earliest of the preclassic cities in the southern Maya

lowlands to erect platforms, temples, stelae, and other forms of monumental architecture. The discovery of these early structures by Richard Hansen and his colleagues on the Regional Archaeological Investigation of the Northern Petén, Guatemala (RAINPEG) Project, now known as the Mirador Basin Project, indicates that by 750 BCE the social, political, and economic complexities associated with the emerging concept of kingship was probably Maya in origin and not Olmec, as previously assumed.

Archaeologists from the University of Pennsylvania discovered Nakbe in 1930 using aerial reconnaissance, but the site was not systematically mapped until 1962, when anthropologist Ian Graham began limited excavations. He named the city Nakbe, which in Yucatec Maya means “on the way.” Intensive investigation of the site commenced in the late 1980s under the auspices of the RAINPEG Project and continues at present. Between 600 and 300 BCE, residents of Nakbe leveled their villages and used the rubble as fill for two substantial platforms that would eventually become the foundation of Nakbe’s civic-ceremonial center. Because of the site’s marshy location, the builders of Nakbe connected these two Middle Preclassic platforms, which extended an impressive approximately 60 to 92 feet (18 to 28 meters) into the air, with the Kan sacbe, an elevated causeway of crushed white stone as high as 13 feet (4 meters) aboveground in certain areas. Another sacbe connected Nakbe to El Mirador, a city located approximately 8 miles (13 kilometers) to the north, whose rise to prominence came on the heels of Nakbe’s demise.

By the Late Preclassic, the eastern and western platforms had reached monumental elevations of approximately 105 and 148 feet (32 and 45 meters), respectively. The city’s principal structures sat atop these two basal platforms. One part of the two-part eastern platform held a terrace surrounded by a number of low platform structures forming a court with a freestanding pyramid abutting it at the western corner; on the other part rested an even larger pyramid that was visible, but not accessible, from the court. The western platform supported three terraced courtyards and associated building complexes, the highest terrace of which was crowned by

Nakbe's largest and most magnificent pyramid. Structure 1, as this pyramid is known, was decorated with four large masks positioned symmetrically on either side of the main staircase leading from the central plaza to the triadic complex of three temples at the top. Maya artisans carved the masks in stone, covered them with stucco, and then painted them in multiple colors. Archaeologists reburied three of the four masks for preservation purposes, but the largest mask remains visible and depicts Vucub Caquix, or Seven Macaw, the principal bird deity associated with royal accession.

Members of Richard Hansen's team also uncovered 45 fragments of a stone stele that when intact measured 11 feet (3.4 meters) in height. The reconstructed stele portrays two men standing face to face and wearing garments similar to those appearing on the granite Miraflores stele from Kaminalijuyu, an indicator of highland-lowland interaction as early as the Late Preclassic. One of the two men points his index finger upward to a severed head, a scene evoking the

mythological genealogy described in the Popol Vuh of the ball-playing hero twins Hunahpu and Xbalanque, whose father's skull grew on a tree after his sacrifice by the cruel lords of Xibalba. Stone quarrying techniques and cutting technology were initial areas of investigation in the RAINPEG Project, as archaeologists wanted a better understanding of how the Maya built such grandiose structures in such a relatively quick period of time. A series of replication studies demonstrated that a variety of chert tools including hammerstones, picks, and axes were efficient, accurate, and durable for shaping limestone.

ERA 4 Expanding Regional Civilizations, 300–1000

During these 700 years, 30 to 35 generations lived, succeeding each other at 20–25 year intervals. Over these seven centuries, the earth's estimated population grew slowly (by modern standards) from perhaps 200 million to 300 million. But that number is deceptive, because although the number of earth's human inhabitants did not even double in nearly three quarters of a millennium, within that period there were significant population blooms and crashes. The rise of great empires brought a modicum of internal peace and security, allowing prosperity to spread and great cities to thrive; the convulsions that accompanied the decline and destruction of great empires brought war, desolation, and depopulation. New crops and agricultural techniques brought significant population increases; environmental degradation and weather fluctuations resulted in famines and precipitous population declines. These centuries constitute an era of rises and falls, of great achievements and appalling catastrophes.

These centuries witnessed periods that for many powerful and wealthy people were halcyon years, serene times in which life seemed to be a great fulfillment.

The Fujiwara regent of Japan in the eleventh century expressed his satisfaction with his time:

“No waning in the glory of the full moon
The world is indeed my world”

During some phases of this era, there were seemingly invincible conquerors and mighty builders who may have shared the sentiments expressed in “Four Preludes to Playthings of the Wind” by the American poet Carl Sandburg:

“We are the greatest,
We are the Best
Nothing like us ever was”

But for many, perhaps most, life was difficult, often desperate. For large numbers of slaves (and nearly all societies had slaves, especially in the Mediterranean region and Asia), life was an unrelieved round of exploitation and degradation. The vast majority of people lived as agricultural peasants, not slaves, but they were subject to landlords and tax

The vast majority of people lived as agricultural peasants, not slaves, but they were subject to landlords and tax collectors and were sometimes vulnerable to marauding bands of robbers and slavers.

collectors and were sometimes vulnerable to marauding bands of robbers and slavers.

For all of their exploitation, and often because of it, these peasants were the strength of their societies, and the vitality of empires was directly proportional to the well-being of the peasants.

Life for many was, to quote the English philosopher Thomas Hobbes, “poor, nasty, brutish and short.” Life expectancy in the agricultural regions dominated by cities, where the vast majority of the people lived, has been estimated to have ranged from 30 to 35 years. Early in the era, pandemics swept through China and the Roman empire and other regions of Eurasia, carrying off untold millions, especially in the cities.

For women in this era, life could be difficult. As was true for nearly all agrarian civilizations since the development of sedentary agriculture, most societies in this era were patriarchal, with many of the benefits of the social order reserved for the men, while women shouldered much of the burden of work and service. During the middle centuries of this era, in the Mediterranean region and West Asia, women were increasingly secluded; in India and China, daughters-in-law came to occupy the lowest rung in the familial order. In the savanna regions of Africa, women’s roles became much more narrow as patrilocal residence became common and the reckoning of descent through the male line spread.

This era witnessed the spreading of great regional civilizations. This was most apparent in the Afro-Eurasian ecumene (the zone of interacting civilizations that at this time included the Mediterranean region, much of western Europe, West Asia, South Asia, Southeast Asia, East Asia, and central Asia), but it was also true, although to a lesser extent, in Africa south of the Sahara as well as parts of the Americas and, coincidentally, the vast area of the Pacific Ocean that historians call East Polynesia.

For the sake of convenience and because it roughly conforms with some major political changes, particularly the rise and fall of some empires, this period can be divided into two sub-eras: the Age of Southernization (300–600 CE) and the golden age of Islam and the Tang dynasty (600–1000). This division works fairly well for the Afro-Eurasian ecumene and, surprisingly, for East Polynesia (the time periods but not the titles of the sub-eras). For Africa south of the Sahara it has less coherence, and for the Americas other periodization schemes may be more appropriate.

The Age of Southernization, 300–600

The term “Age of Southernization” is appropriate for the period 300–600 because during these centuries the great center from which many of the cultural innovations in the Eastern Hemisphere radiated was South Asia, better known as the Indian subcontinent. This Age of Southernization is thus analogous to the nineteenth- and twentieth-century Age of Westernization, when many cultural innovations emanated from Europe and North America (i.e., the West).

Northern Indian prosperity during the Gupta dynasty (ca. 240–555) generated the cultural process for which the Age of Southernization is

named. The Gupta empire, roughly contemporaneous with the Sassanian empire (226–651) in Persia and the early phase of the Byzantine (East Roman) empire, was a cultural dynamo, during which great strides in metallurgy, mathematics, medicine, and philosophical and religious speculation were made.

The Age of Southernization also witnessed the radiation of Indian civilization to Southeast Asia, East Asia, and central Asia and, to a lesser extent, the Mediterranean. Indian crops, such as cotton, rice, bananas, and citrus fruits, spread west; Indian technology, such as the art of distillation, followed the trade routes. Indian music and musical instruments, such as the cithar (a forerunner of the guitar), and Indian mathematics, with its decimal system and the concept of zero, were carried in the baggage of merchants, missionaries, and conquerors. Indian religions and religious forms also traveled: Hinduism and Buddhism into Southeast Asia, Buddhism into central and East Asia, and some Buddhist ideas, as well as the practice of monasticism, to the Mediterranean region.

In Southeast Asia, merchants and other travelers transplanted Indian civilization to such an extent that Southeast Asia during this period has been called “Greater India.” States, modeled after the Hindu kingdoms in India, were established on the Southeast Asian mainland among the Khmers, the Mons, and the Chams and also among the Malays and others of the Malay Peninsula as well as the large islands of Sumatra and Java. In the Southeast Asian mainland and island kingdoms, varieties of Hinduism, Buddhism, or both were established as court religions.

Merchants and missionaries carried much of Indian civilization, including Buddhism, over the Hindu Kush and into Afghanistan, Iran (Persia), and other regions of central Asia. From central Asia, Buddhism spread along the Silk Roads to China. Buddhism became an important religion in China during the Period of Division (220–589) from the fall of the Han to the rise of the Sui dynasty. Other aspects of Indian civilization, especially art motifs, music and musical instruments, science, and mathematics, went with Buddhism from India to China. By 600 this complex of ideas and traits was naturalized in China. In the next two centuries, this new Buddhist Chinese civilization spread to Korea and Japan.

Indian civilization influenced the Mediterranean region during the early centuries of this period less than it did central and East Asia, and its influences were, for the most part, less direct and less obvious. Although especially in the fourth and fifth centuries there was direct commerce between the Mediterranean peoples and the Malabar Coast of southwestern India, most Indian influences reached the Roman empire through the mediation of Sassanian Persia, or Arab traders, or through the Ethiopian port of Adulis. Although Indian mathematics did not reach Europe until after the year 1000, some historians believe that certain religious notions, as well as religious practices, diffused from India to the pre-Christian and Christian West before and during the

Other aspects of Indian civilization, especially art motifs, music and musical instruments, science, and mathematics, went with Buddhism from India to China.

early centuries of this period. The idea of Sunday as the holy day of the week, the practice of putting solar disks (nimbus and halos) around the heads of gods and saints in religious art and important personages in secular art, and the establishment of monasteries, where a special religious elite, often celibate, sanctified the society—all were features of the flow of cultural forms from India, often by way of Persia.

Although cultural currents were diffusing from India and China to the Roman empire, the most significant development in the Mediterranean region during the three centuries (300–600) was the rise of Christian civilization in the Roman empire and the Germanic kingdoms that were the successors of the empire in the west. Roman emperor Constantine (r. 306–337) favored Christianity in the first quarter of the fourth century, and it became the official religion of the empire in 380. Latin, or western Roman, Christianity became the vector by which the modified and impoverished Graeco-Roman civilization spread to the Germans, who invaded the western empire in the late fourth to mid-sixth centuries, and to the Celts in Ireland and Scotland. Meanwhile, trade and missionaries were spreading Christianized Graeco-Roman civilization east into Mesopotamia and the Caucasus and south into Ethiopia and the area on the great bend of the Nile River known as Nubia (the area of the modern republic of Sudan).

The great surge of cultural influence from India was contemporaneous with a swelling tide of migration and military influence from the grassland pastoralists and forest dwellers of Inner Eurasia. In that vast region stretching from the Rhine River border of the Roman empire in the west to the borders of China in the Ordos steppe, unexplained phenomena occurred during these centuries, causing immense migrations and population displacements.

All the neighboring sedentary peoples, including the Chinese, the Sogdians (an eastern Iranian people inhabiting the area of present-day Uzbekistan), the Indians, the Persians, and the Romans, were impacted. Invaders from the steppe and forests north and west of China, known to the Chinese as “the five barbarians,” seized northern China from the Jin dynasty. In the west, Goths from north of the Black Sea drove the Romans south of the Danube River after 376. Later, the Huns, another group of invaders from the steppe, set in motion a great movement of peoples into Europe that resulted in the fall of the western Roman empire and the rise of Germanic kingdoms. Farther east, the central Asian Hephthalites invaded and terrorized Persia and India, while the Toba erected their empire on the northern Chinese plain.

Throughout this period, groups of Turkish pastoralists expanded in the Eurasian steppe. They coalesced into great empires, such as the Tork empires (sixth century to eighth century), the Khazar empire (early seventh century to the late tenth century), and the Uighur empire (744–840). These steppe empires taxed and protected transhemispheric trade on the Silk Roads. Sometimes they conquered sedentary agricultural peoples. Occasionally, the conquered people, as in Bulgaria, assimilated them but, as frequently, Turkish peoples imposed their languages and ethnicity on the conquered people, as in Turkey (Anatolia) and central Asia well after the year 1000.

While crops and cultural forms were diffusing from India to the West, out of the Arabian Desert came another cultural feature that would, by the middle of this period, revolutionize human adaptation to the Sahara and provide a cultural and trade connection between the great Afro-Eurasian ecumene and Africa south of the Sahara. This cultural feature was the domesticated single-humped camel, or dromedary, with the new camel saddle, the use of which had begun to spread from Arabia into the Sahara region in the last centuries BCE. By the fourth or fifth centuries CE, camel nomadism was becoming ubiquitous throughout the Sahara, and camel caravans were extending trade across the Great Desert, especially into the savanna regions of West Africa. From then on, the Sahara was less of a barrier. While it remained a great obstacle to cultural exchange, this vast wasteland was becoming increasingly porous. While most of Africa south of the Sahara did not become an integral part of the great Afro-Eurasian ecumene until well after 1000, all parts of Africa were to be impacted by developments from the ecumene in this period.

While cultural influences emanating from the Mediterranean region across the Sahara were important and would, by 1000 CE, work a religious and cultural transformation of the Sudan, that great belt of grassland, or savanna, between the desert and the tropical forest, an equally important influence moved in from the east, across the Indian Ocean and the Arabian Sea. In trading posts and cities established along Africa's east coast, Austronesian, Indian, Arab, Ethiopian, and Bantu merchants and settlers began growing Asian crops, including rice, cotton, citrus fruit, sugarcane, taro, and especially bananas. These crops would, in the course of this period, spread from Africa's east coast to all parts of Africa south of the Sahara. Eventually, the addition of bananas to the agricultural portfolio would lead to a remarkable population increase and the emergence of states and empires in the African forest and savannas.

One of the last phases of the great Austronesian dispersal provided an important impetus in the growth of cultural influences in Africa from the Indian Ocean. Sailors and settlers from Indonesia to East Africa and particularly Madagascar comprised the western wing of the Austronesian dispersal, while thousands of miles away in the central and eastern Pacific Ocean, the Polynesian exploration and settlement of the Society Islands, the Marquesas, Hawaii, Easter Island, and, perhaps after 1000 CE, New Zealand (Aotearoa) represented the Austronesian Far East. Because of these epic migrations, the Austronesian language group was more widespread than any other until after 1500.

The Austronesians who settled Madagascar probably began migrating from Indonesia to that great island before 300 CE and continued to come after 1000 CE. In Madagascar, Indonesian immigrants assimilated Bantu groups and, from there, modified the cultures of continental Africa south of the Sahara. One modification was in music and musical instruments. The Africans widely adopted the Indonesian xylophone, or marimba.

By the fourth or fifth centuries CE, camel nomadism was becoming ubiquitous throughout the Sahara, and camel caravans were extending trade across the Great Desert, especially into the savanna regions of West Africa.

The period that comprises the Age of Southernization coincidentally marks a natural period in the growth of East Polynesia. Despite that, for all practical purposes, cultural communication between the ancestors of the Polynesians and Eurasia had ended several thousand years prior to this period. Anthropologists believe that Polynesian culture developed from Lapita culture in the Solomon Islands, perhaps 2000 BCE. The early Polynesians settled West Polynesia (Samoa, Tonga) sometime in the second millennium BCE. After settling West Polynesia, migration stopped; there was a long pause for 1,500–2,000 years. Then, for reasons that anthropologists have yet to discover, about 300 CE (the beginning of this period) a few Polynesians began to voyage thousands of miles east, rapidly exploring most remaining Pacific Islands and making initial settlements on most by 650 CE except Aotearoa (New Zealand).

The Golden Age of Islam and the Tang Dynasty, 600–1000

Just as the Age of Southernization is so-named because cultural innovations emanating from India impacted much of Afro-Eurasia, in the golden age of Islam and the Tang dynasty, roughly 600–1000, the great founts of cultural innovation were Tang China and the newly minted Islamic civilization. For these centuries (and perhaps an additional six centuries after 1000, a millennium in all) China and the Islamic world were the two cultural and economic dynamos of the expanding Afro-Eurasian ecumene. These two centers were magnets of cultural attraction, and their interaction resulted in a fruitful cultural synergy. China was preeminent for most of the era's innovations in material culture and developed papermaking, gunpowder, printing, and many agricultural and industrial processes. The Muslim world (known as Dar al-Islam, or House of Islam) served as a transmission belt that carried Chinese innovations to the far corners of the Afro-Eurasian ecumene during this period and for centuries after.

Throughout this period, China was the most populous, the most prosperous, the most urban, and the most technologically innovative civilization in the world. For much of this time, China also wielded the strongest military force. With the imposition of imperial peace after the

reunification of China by the Sui in 589 and then the Tang in 618, the stage was set for a glorious flowering of creativity. New canals, bridges, and roads led to new heights of prosperity. New lands were settled, cities flourished, and the imperial government enjoyed mounting revenue surpluses. With the growing opulence of

With the imposition of imperial peace after the reunification of China by the Sui in 589 and then the Tang in 618, the stage was set for a glorious flowering of creativity.

Chinese society came a heightened development of Chinese art and literature. At the high noon of the Tang dynasty, in the long reign of Xuanzong (r. 712–756), Chinese civilization experienced a surge of creativity that recalls the glories of fifth-century BCE Greece. But by the middle of the eighth century, the security and serenity of Tang had ended, and

China experienced An Lushan's Rebellion, a disaster that the Tang endured but from which it never really recovered.

Chinese civilization under the early Tang dynasty was powerfully seductive to the neighbors of China. Its wealth and art, as well as the strength of its government, exerted a forceful attraction over the ruling groups in surrounding lands, particularly Korea and Japan, who sought to emulate Tang China's greatness by wholesale adoption of Chinese civilization. Students were sent to China to study Buddhism as well as Confucianism and Chinese manners and morals.

The Yamato chieftains of Japan sent eight great embassies to China between 607 and 838 with hundreds of students whose mission was to learn the secrets of Chinese state power and to use this knowledge to construct an equally powerful Japanese state. The Japanese built a capital city, huge for its time, in imitation of the Tang capital, Chang'an. The city was replete with great Buddhist monasteries and a highly cultured, but idle and inbred, class of aristocrats.

In this city, then called Heian but now known as Kyoto, aristocratic courtiers and ladies enjoyed a luxurious and mannered existence, characterized by ritual and intrigue, that lasted until the second half of the twelfth century. Out of this hothouse civilization emerged humanity's first great novel, *The Tale of Genji*, by the court lady Murasaki Shikibu.

The rulers of the Korean kingdom of Silla also built a huge capital city in imitation of Tang. Silla, in alliance with Tang China, united the Korean Peninsula in 668 after centuries of division into three Korean kingdoms. The Silla dynasty, assimilating Tang civilization, including Buddhism, even more thoroughly than Japan, lasted until 935, when it was replaced with the Koryo dynasty.

At least two more states arose in imitation of Tang: Parhae, which persisted for two centuries (713–926) in the northern part of Korea and much of Manchuria, and Nanzhou, which prospered in China's southwest from 751 until it was conquered by the Mongols in the thirteenth century.

While Tang China's civilization was adopted as a whole package by its neighbors in East Asia, only selected, mostly technological features from China influenced other peoples, including those of the Muslim world. The meeting of Tang China and the Islamic world was intense when their armies fought each other in the Battle of Talas in 751, in the Ferghana Valley of central Asia. By that time there had been contact between China and the Muslims for over a century, almost from the foundation of the Islamic religion.

The roots of Islamic civilization can be traced to the early seventh century, when the Prophet Muhammad (ca. 570–632) began preaching the new religion and nurturing the Muslim *umma*, or community of believers. Because Islam, the youngest of the great world religions, was the only one originating within the period from 300 CE to 1000 CE, and because a dynamic new empire and civilization, which has been called the first world civilization, developed around this new religion, Muhammad was the outstanding individual of this period, the superhero of the time.

The sudden emergence of Muslim power from out of the Arabian Peninsula in the early seventh century was surprising but not

unprecedented. The Byzantine empire and the Sassanian empire had exhausted each other in their series of terrible wars that lasted a century and a quarter. The populations of both empires were alienated from their governments. Far from assisting the imperial forces in repelling the Muslims, many of the subject peoples in Iraq, Syria, Palestine, and Egypt welcomed the invaders and often assisted in the conquest. What was more amazing than the easy Muslim conquests was the durability of the Muslim state and the development of Islamic civilization. In little more than three or perhaps four generations (86 years) Muslim armies carved out the largest empire the world had known, extending from the Bay of Biscay in Europe to the mouth of the Indus River and including what had been the wealthiest and most prosperous lands of the Roman and Sassanian empires. Throughout this vast area, Arab armies settled in garrison cities: Kufra, Basra, and Qum in the former Sassanian empire; Merv in central Asia; Fustat in Egypt; Qayrawan in Tunisia; and others. These garrison towns acted as centers for spreading the Arab language and Islamic religion, and within less than a century, in many areas, the surrounding countryside was Arabic in language with a majority of Muslims. Arabic replaced the ancient languages of Egypt, Syria, and Mesopotamia as well as the Latin creole tongues of the Maghreb (western North Africa). However, Arabic failed to replace Persian, which emerged as one of the chief literary languages of the Muslims.

Muslim civilization is basically a Western civilization, but it has been called the first world civilization because it eventually spanned the Eastern Hemisphere from the Atlantic to the Pacific and interacted with most of the other civilizations of the Eastern Hemisphere (except those of Oceania). The Muslims inherited much of their basic science, mathematics, philosophy, and cosmology from their predecessors in the Mediterranean and Iranian lands, but they were equally quick to appropriate elements from India and China. The central bond of the Islamic world, the Muslim religion, is, like Judaism and Christianity, originally Semitic, and like its sister Abrahamic faiths, it owes a great debt to Persian Zoroastrianism. From Persia, Islamic civilization acquired its concept of kingship and a philosophy of government as well as a great trove of literary and historical lore. From India came mathematical concepts, such as the decimal system and Arabic numbers.

The Muslim world assimilated a large body of agricultural and industrial technology and crops from India as well. From China, the Muslims acquired many material innovations without which modern civilization would have been much different: paper, new methods of harnessing horse traction, improved water and wind mills, improved mining technology, a vastly expanded pharmacopoeia, and much else.

Tang China and the Muslim world interacted in ways that stimulated both. Chang'an and Baghdad, the capitals of the Tang dynasty and Abbasid caliphate, had large populations of wealthy courtiers enjoying the surplus collected from the renewed prosperity of rich agricultural lands. These courtiers exerted a demand for exotic luxury goods that could only be satisfied through long-distance trade. The most important routes of this long-distance trade were the overland caravan silk routes

across the Eurasian steppe from China to Baghdad and Constantinople and the seaborne trade through the Indian Ocean and the China Sea.

The overland Silk Roads and the Indian Ocean–China Sea route were the main trunk routes for what became, by the middle of this period, a great trading system that spanned the Eastern Hemisphere, reaching from Japan and the islands of the Indonesian archipelago in the east to the forests of West Africa and northern Europe in the west. It was the circulation system of the great cultural ecumene, and the center of this hemispheric circulation system, the heart of the ecumene, was the Muslim world.

Though the Muslim world was the heart of the ecumene, the vast Chinese economy provided much of the stimulus for this trade. The Chinese were nearly self-sufficient in most products, but they were deficient in some essentials and many luxuries. Warhorses from central Asia were especially in constant demand, and the search for a supply of these horses was a force that drove much of the trade on the Silk Roads. But the Muslims wanted Chinese luxuries, principally silk, that they paid for with silver from central Asia. Silver coins from the Abbasid caliphate were the currency of the time, a common coin from China to the western Mediterranean.

Warhorses from central Asia were especially in constant demand, and the search for a supply of these horses was a force that drove much of the trade on the Silk Roads.

Trade through the Mediterranean Sea had diminished considerably with the fall of the western Roman empire and the Islamic conquest of the Maghreb (western North Africa), but by the late eighth and early ninth centuries it was recovering. The emergence of the Carolingian empire by 800 stimulated this. Feeding into the Mediterranean routes were trails to northern Europe, bringing luxury goods north and forest products and slaves to the more urbanized south. Even the far north of Europe entered into the mainstream of hemispheric trade.

The Vikings erupted from Scandinavia in the late eighth century, marauding and pillaging and sometimes conquering the coast lands of western Europe and the forest peoples of eastern Europe, seizing tribute in amber and furs but especially slaves to trade for Abbasid silver and, through Muslim intermediaries, Chinese luxuries. The Vikings established a trading and tribute-gathering kingdom on the Dneiper River that emerged, by the end of the tenth century, as Kievan Rus (the ancestral state of both Russia and Ukraine).

The Indian Ocean–China Sea route competed with the overland Silk Roads as the principal artery of the Eastern Hemisphere trading system. The great sea route ran from Japan and Korea to Chinese ports on the Shandong Peninsula and from there south along the China coast to the great port of Guangzhou. Arab, Persian, Indian, and Malay merchants frequented Guangzhou, and thousands of Arabs and Persians lived there, buying Chinese silks, ceramics, and other luxuries and selling ivory, rare woods, and metals from around the Indian Ocean littoral. From Guangzhou, the sea route ran south, through waters infested with Cham pirates, to the port of Srivijaya in western Sumatra. As the capital

of a trading empire, Srivijaya maintained a navy to suppress the pirates who frequented those shores. Srivijaya was home to a large Buddhist monastery/institution of higher learning and was a stopover for East Asian Buddhist pilgrims on the road to Nalanda, the great Buddhist monastery in Bihar, India. Srivijaya was a major resting place for travelers and a meeting place for Chinese and Indian merchants.

In Srivijaya, a tributary stream of trade, carrying spices from the Moluccas and rice from Java, joined the main Indian Ocean trading system. The sea route ran west from Srivijaya across the Bay of Bengal to Mahabalipuram and other ports in southern India. A small fraction of the trade went north instead of west, to the Khmer kingdom of Cambuja (Cambodia) and the Mon kingdoms on the Irrawadi River. These Southeast Asian states had adopted Indian civilization and imported Chinese silk and other luxuries for ivory and exotic products used in Chinese medicine.

The majority of the trade continued on from Mahabalipuram to sail around the southern tip of India to the Malabar Coast. There, the ships waited until the monsoon season, when they would sail west across the Arabian Sea. India also contributed much to the westward traffic, in pepper, gems, and other products.

This oceanic trade route bifurcated in the Indian Ocean. The main stem ran up the Persian Gulf to ports in Persia and Basra in southern Iraq, the port of the sea route's main western market, Baghdad. A second oceanic route ran to southern Arabia and into the Red Sea, to reach the Ethiopian port of Adulis. From the fourth to the eighth centuries, the Axumite empire of Ethiopia was one of the chief trading powers on the Indian Ocean route, as hoards of Ethiopian (Axumite) coins in southern India and Indian coins in Axum attest.

During the period of Axumite trading prominence, much of the Indian Ocean trade was going up the Red Sea, eventually to end up in Alexandria in Byzantine Egypt, but camel caravans also carried much overland along the western side of the Arabian Peninsula to Byzantine Syria. According to some scholars, the prosperity created by that carrying trade through Mecca widened economic disparities, causing social instability that made the Arabian society fertile ground for the religious turmoil that led to the emergence of Islam.

The Indian-Ocean trade system reached far south along the East African coast. There, commercial city-states grew up whose people spoke Swahili, a language of the Bantu family with Arabic influences. The Swahili traded African products, particularly elephant ivory, smelted iron, and perhaps gold from the interior (after 900) for Chinese and Indian goods. The Swahili also adopted, perhaps from Indonesian migrants who may have briefly tarried on the East African coast en route to Madagascar, Asian crops: Asian rice, Asian yams, taro, sugarcane, and especially bananas. These crops took root in East Africa early in this period, but by 1000 they had diffused throughout most of Africa south of the Sahara, reaching across the continent to the Atlantic coast of West Africa by the tenth century. These crops did not replace the traditional African crops but rather supplemented them, resulting in a greatly increased food production. This resulted in greater populations

in most areas. Eventually, the greater population density led to the emergence of many new states by or shortly after the eleventh century.

While East Africa's participation in the Indian Ocean trading system was strengthening Africa's connections with the Afro-Eurasian ecumene, the growing involvement of West Africa in the trans-Saharan trade connected Africa south of the Sahara with the Mediterranean end of the great ecumene. Trade across the Sahara existed from at least the first century CE, but it expanded greatly during this period with the increasing use of Arabian camels in the Sahara.

In the early centuries CE, camel pastoralism had spread throughout the great desert, and by the seventh century, Berber merchants developed an institutionalized system of camel caravans traveling three main routes across the Sahara. Gold, slaves, kola nuts, and alum traveled north, while handicraft goods, salt, religious specialists, horses, and weapons went south. Cities on the edge of the desert served as ports from which the caravans set forth. Sijilmasa on the northern edge of the great desert and Khumbi Saleh in the western Sudan were the chief ports on the western route. On the central route, the kingdom of Zawilla, in the Fezzan oases, dominated the trade that flowed from the Sudanese empire of Kanem, located on Lake Chad. Other great empires grew up south of the desert, such as Ghana. These empires grew wealthy and powerful, partly through the trans-Saharan trade. Their rulers employed Muslim Berbers to staff their administrations, but during this period, the mass of their people remained pagan.

Ghana, Kanem, and the other Sudanese kingdoms traded salt obtained from the Sahara trade for gold and kola nuts from the forest peoples to the south and west, using the Niger River as a highway. These peoples of the West African rain forest were becoming more numerous, and their large villages were evolving into city-states. Many of these city-states started as colonies of the Yoruba mother city of Ife, which served as the spiritual center for Yoruba land. The Nri kingdom was another important West African forest state that dominated the Igbo people by religious sanctions rather than military prowess.

Before 1000, political entities larger than city-states had evolved among only a few of the numerous agricultural peoples inhabiting most of the West African forest, the equatorial forest of central Africa, or the Great Lakes region of East Africa. In those areas, the autonomous agricultural village was the rule.

The Bantu-speaking peoples, who completed their expansion from the Nigerian-Cameroon border to dominate central, East, and southern Africa by the beginning of this period, were originally a yam-growing matrilineal forest people, but in assimilating numerous groups of cattle-raising and grain-growing peoples were becoming patrilineal cattle pastoralists in the eastern and southern Africa savannas. They were skilled artisans, smelting iron and copper and weaving superior cloth.

In eastern Polynesia, almost all of the inhabited islands were settled in the 350-year surge after the beginning of this period. During this early phase, a light population spread out among the great archipelagos from the Marquesas to Tahiti to Hawaii and Easter Island, living in

relatively egalitarian societies and subsisting on the species endemic to the islands. After about 650, the early phase of eastern Polynesian history was over. Many of the indigenous easy-to-catch species had been hunted to extinction, and much more intensive agricultural practices, necessary to feed much larger populations, developed. Fishponds, terraces, and irrigation works began to be constructed by populations living in large villages in which increased social stratification was developing.

It was during this time that Polynesian voyagers reached the western coast of South America and returned to islands as widely separated as Hawaii and Easter Island with the knowledge of sweet potato cultivation.

Between 650 and 1000 CE, long-distance voyaging continued in the Polynesian Islands, and contact, perhaps sporadic, between archipelagos as distant as Tahiti and Hawaii continued. It was during this time that Polynesian voyagers reached the western coast of South America and re-

turned to islands as widely separated as Hawaii and Easter Island with the knowledge of sweet potato cultivation.

Two centuries after the settlement of Easter Island in the Pacific, the Scandinavians were settling Iceland (874) in the Atlantic, thus completing the occupation of most inhabited lands (with the possible but not certain exception of New Zealand).

The Americas

During this period (in fact during most of history before Columbus's famous voyage in 1492) events in the Americas were isolated from those in Afro-Eurasia: each hemisphere existed in almost hermetic isolation from the other. While it is true that some contact between the two nearly isolated regions probably did take place before or during this period (the Viking explorations of coastal North America occurred mostly after 1000 CE), they were sporadic and, with two exceptions, insignificant.

These exceptions were

- a) The diffusion of bow and arrow technology by proto-Inuit hunters migrating from Asia across the Bering Sea to North America in the early centuries CE. The bow and arrow then diffused southward from group to group in North America and probably produced a spasm of instability as it progressed southward through the continent.
- b) The acquisition of sweet potatoes (kumara) by Polynesian mariners visiting South America sometime between 650 and 900 CE. While sweet potatoes became an important crop in many parts of Polynesia, the Polynesians left little discernable trace of their visit.

Although the Americas were isolated in their own solitude and were little influenced by events external to the Americas (except for global meteorological and environmental phenomena), the years between 300 and 1000 CE form a coherent period for some important areas, especially the classic Maya, in the Americas. But for many other

areas, the periodization is, at best, uncertain and attempts to describe their pasts in terms of periods derived from the Eastern Hemisphere may seem contrived and artificial. However, if we allow broad flexibility of perhaps several centuries, it is possible to discern some parallels between the histories of the hemispheres.

There was no great zone of cultural interaction and diffusion in the Americas comparable to the great hemisphere-wide Afro-Eurasian ecumene. There were no world religions, such as Buddhism, Christianity, and Islam, sweeping through large reaches of the Americas. There was no great trading system on the scale of the interconnected Silk Roads, Indian Ocean routes, and trans-Saharan system. Instead, in the first millennium CE, there were six or more regions that served almost as regional ecumenes. Each of these offered cultural interaction within itself but interacted much less with outside groups.

The two principal regional ecumenes in the first millennium Americas were Mesoamerica and the Andes. These two cultural collectives were the only areas in the Americas where significant urbanization occurred. There, the first states emerged.

Mesoamerica consisted of a group of cultures and peoples in central and southern Mexico as well as northern Central America. This was the only area in the Americas in which true writing systems developed. In Mesoamerica, intensive agriculture supported relatively dense populations. Kingdoms, such as the Zapotec kingdom of Monte Alban, emerged during this period.

Teotihuacan, in central Mexico, was the largest city in the Americas. Until it experienced disaster in the beginning of the seventh century, Teotihuacan was the great power of Mesoamerica and exerted some control over the Mayan cities to its south.

The Maya classic period (250–900 CE), when the lowland Mayan were constructing stone monuments dated by the Long Count, is almost entirely encompassed in this period. Because their writing system has been deciphered, more is known about the Maya than any other people in the Americas before 1000 CE. Their glyphs, incised in stone, tell us that the Maya city-states were very warlike, much like the Greek city-states a millennium earlier. Also like the Greek city-states, they were culturally very creative, making advances in astronomy and mathematics especially. Early in this period, in India and among the Maya, mathematicians discovered the concept of zero independently of each other. The classic Maya flourished until the tenth century, but then a series of catastrophes resulted in the abandonment of its cities and the collapse of classic Maya civilization.

Andean civilization was the other regional ecumene in the Americas, which had both cities and states. The Andean region was the home of one of the most unusual of the world's urbanized civilizations, unique in several aspects. With practically no contact with non-American peoples

Their glyphs, incised in stone, tell us that the Maya city-states were very warlike, much like the Greek city-states a millennium earlier. Also like the Greek city-states, they were culturally very creative, making advances in astronomy and mathematics especially.

and almost no direct relationship with Mesoamerican civilizations, the peoples of the mountains and coastal valleys of Peru had, by 300 CE, developed cities and states.

Unlike Mesoamerica, Andean civilization had nothing that modern historians can recognize as writing, so what we know about it before 1000 is the fruit of archaeology. The peoples of Andean civilization, like the Mesoamericans, were excellent farmers, cultivating cotton, potatoes, maize, and about a dozen other crops on raised gardens, mountain terraces, and irrigated river valleys.

Their cities, such as Nazca, Moche, Tiwanaku, and Wari, were often built on or around great pyramidal mounds. They were excellent craftsmen, producing what some consider the finest ceramics in the Americas. Metallurgy, which was unknown at this time to the Mesoamericans, was a highly developed craft in Andean civilizations. (During the first millennium CE, the art of smelting metals was slowly diffusing northward to reach Mesoamerica roughly by 1000 CE.)

Nazca, a city and state, prospered as a ceremonial center on the coastal plain of southern Peru until the ninth century and produced the mysterious Nazca lines in the desert.

The city and state of Moche is known to us through its beautiful and magnificently wrought pottery and often comic and even pornographic ceramic effigies, highly developed metallurgy, and huge mounds built of earth and adobe bricks, known by moderns as the Huaca del Sol and Huaca de La Luna (Pyramid of the Sun and Pyramid of the Moon, respectively). In their time, these were the largest man-made structures in the Americas and are evidence of a powerful government, regulating the religious as well as economic lives of its people.

Moche flourished on the northern Peruvian coast from about 100 to 750 CE, when a cataclysmic flood, perhaps caused by a super El Niño event, destroyed it. Moche culture carried on in new urban centers such as Galindo and Pampa Grande.

Tiwanaku and Wari repeated the pattern of rise and fall that Moche had experienced. For both Tiwanaku and Wari, the last half of the first millennium CE were years of prosperity and power. For both, the years of plenty abruptly ended with the onset of the terrible three centuries of drought that began about 950.

Tiwanaku, located in modern Bolivia near the shore of Lake Titicaca, may not have been an empire in the modern sense. Tiwanaku owed its prosperity to the amazing productivity of its raised gardens in the Titicaca wetlands and became an imperial power by circa 500 CE. This imperial city established an archipelago of colonies in a variety of ecological zones to provide it with products, which could not be obtained locally. For more than half a millennium the population increased, and the elite of Tiwanaku's class-ridden society prospered, building luxurious dwellings. In the middle of the tenth century the prolonged drought destroyed Tiwanaku's agriculture, and the city was deserted.

Wari, in the central mountains of Peru, was the capital of an empire that controlled much of Peru during 700–950 CE. Wari was a militaristic city whose power bordered that of Tiwanaku in the south and

Moche's successors in the north. Wari tied its far-flung empire together with a web of roads along which messengers traveled carrying quipu messages. Wari's power was also rooted in agriculture (the carefully terraced irrigated gardens in the Ayacucho basin), and its prosperity and empire ended by the same drought that humbled Tiwanaku.

Between the Andes civilization and Mesoamerica were the cultures of Colombia and Central America. Although not urbanized and without organized states, these cultures practiced a rather highly developed agricultural technology. Some of their people were highly skilled artisans, especially in gold and copper metallurgy. They lived in large villages and were governed by hereditary chieftains.

To the north of Mesoamerica were the Pueblo cultures of the North American Southwest, and the Mound Builder culture of central and eastern North America. There is evidence that regular trade between Mesoamerica and some of the Pueblo cultures took place and that there was some diffusion of culture between Mesoamerica and the Pueblo cultures. At the beginning of this period, the Pueblo peoples practiced some agriculture, raising squash as well as some indigenous crops. About 400 CE they acquired maize, and a few centuries later they acquired beans, both of which had diffused to them from Mesoamerica. The Pueblo cultures are called Basket-maker cultures for the period 100–700 CE, but after that various groups, of the so-called Anasazi (the Navajo term for “Ancient Ones”), succeeded them. (Most Pueblo peoples reject Anasazi, preferring “Pueblo Peoples.”)

There is evidence that regular trade between Mesoamerica and some of the Pueblo cultures took place and that there was some diffusion of culture between Mesoamerica and the Pueblo cultures.

Between Mesoamerica and the Mound Builders, there probably was contact, but the state of our knowledge of this is so embryonic that it is difficult to gauge the extent of that contact. At the beginning of this period, the Mound Builders grew locally domesticated crops, such as goosefoot and sunflowers, but in the ensuing centuries, they acquired first squash and then, a few centuries later, maize. It was not until about 800, at the beginning of the Mississippian period, that they acquired beans, the last of the three sisters of Mesoamerican agriculture.

The Mound Builders are so-called because they built huge earthen mounds, both for burial mounds and as platforms on which to erect their temples and other structures. In general, there were three phases of the Mound Builder cultures: Adena, 750 BCE to about 100 CE; Hopewell, 100–500 CE; and Mississippian, 800–1500 CE.

The Mound Builders, both the earlier Hopewell and the later Mississippian, traded extensively: their trade networks extended from the Rocky Mountains to the east coast and from the Great Lakes region to the Gulf coast.

Most knowledge of the Mound Builders is based on archaeology. Before 1000 CE, all of our inferences about the Mound Builders are based on archaeology. Cahokia (in modern East St. Louis, Illinois), which most archaeologists estimate was a Mound Builder city of tens of thousands of inhabitants, was probably built after 1000 CE.

In the Amazon basin of South America, archaeologists have, in recent decades, discovered another hidden and forgotten but apparently extensive agricultural civilization. Little is known about this civilization, but it was probably thriving during this period. It thrived in large agricultural villages along the banks of the many rivers of the Amazon basin that presumably were used as trading routes for a vast trading network, rivaling that of the Mound Builders of the Mississippi Valley.

Conclusion

In the nearly three quarters of the first millennium CE that this period encompasses, many historical processes were in operation, but five factors stand out:

- 1) The leading roles of India and then China and the Islamic world as cultural innovators and leaders in the Afro-Eurasian ecumene.
- 2) The development of a network of hemispheric trade routes that facilitated cultural contacts and interaction and transfers of culture, technology, crops, and diseases as well as people.
- 3) The growth and spread of three great world religions, first Buddhism, then Christianity, and then Islam. These religions expressed the culture and definition of civilizations as well as served as vectors or carriers of cultural traits from civilization to civilization.
- 4) Isolated as they were from the Eastern Hemisphere, two regions in the Americas, Mesoamerica and the Andes, developed densely populated agricultural societies with cities that grew into states.
- 5) In most of the rest of the earth's agricultural regions—for example, in North America in the Southwest and the Southeast; in Central America and northern South America; in the Caribbean and the vast stretches of the Amazon Basin; in the regions of Oceania known as Polynesia, Micronesia, and Melanesia; and in much of the West African forest, central Africa, East Africa, and southern Africa as well as northern Europe and much of eastern Europe—a less dense population dwelt in nearly autonomous villages, sometimes egalitarian but often governed by hereditary chieftains. They usually had no writing; we know of them mostly through archaeology, the reports of neighboring peoples, or by their own legends and (often unreliable) oral history.

These five factors helped shape the cultural milieu in which the great majority of humanity lived during this period. However, small but significant groups of people lived by other means than agriculture. There were the pastoralists and animal herders who inhabited the Eurasian steppe and the African pastoralists who, during this time, were spreading in the great savannas east and south of the great African equatorial forest. There were also the camel nomads, who had been known in the Arabian desert for centuries but whose way of life spread throughout the great Sahara Desert in the early centuries of the Common Era.

And finally, there were the hunter-gatherers, those who foraged for a living and whose way of life was often nomadic. These groups usually roamed the less bountiful regions of the earth (but there were important exceptions, such as the acorn- and mesquite-eating villagers of California or the salmon catchers and marine mammal hunters of the Pacific Northwest). Although they are often thought of as people without history, especially the Australian Indigenes, who are said to have lived in “dream time,” there were at least some changes in their cultures during the first millennium CE. Some of these changes were the spread of reindeer domestication among the Arctic peoples of Eurasia, the development of new hunting technology among the Dorset and Thule Inuit people, and the introduction and diffusion of the bow and arrow in North America. As the tools of archaeology and historical linguistics are further developed, it is hoped that the cloud of our ignorance that envelops these groups will be dispelled.

Environment and Population

In 536 CE a massive tropical volcanic eruption, one of the most colossal in 50,000 years, shot several cubic miles of dust and sulfurous gas into the atmosphere. The dust and gas were borne aloft to the stratosphere, where much of it remained for the next several years, blocking out much of the sunlight and cooling the atmosphere several degrees. For several years, in many parts of the world, there was frost and snow every month of the summer, accompanied by weak or nonexistent summer monsoons and widespread drought. Crops failed, and famines followed in many countries. The members of the generation that experienced these calamities could well believe that they lived in the end of times, but the suffering caused by these global disasters ended after a decade or two. Civilizations continued as they had before the eruption, but they never escaped the implacable fate determined by the environmental challenges and human response.

This essay discusses the role of environmental evolution and changing population numbers in the expansion of regional civilizations during 300–1000 CE. It describes the environmental cards that fate dealt human societies and the way these societies played them; it talks about rises and falls of civilizations. The focus of this essay is on climate change and agricultural adjustment; expansion of croplands and population growth; years of plenty and abundant harvests; cold and dry times when famine struck and populations fell; the cutting of forests and the construction of great cities; deforestation and environmental degradation; hunger and epidemic disease; the flowering of civilizations in salubrious times and their decline and sometimes collapse in times of drought and cold; land subsidence, the flooding of coastlands, and the building of dikes; volcanic eruptions; and El Niño events.

The seven centuries of this era (300–1000 CE) straddle two climate periods: the Dark Age Cold Period (200–650) and the Medieval Warm Period (800–1300). There is much disagreement about the beginning and ending dates of these periods; some would date the Dark Age Cold Period at 150–700 CE, while others would delay the start of the Medieval Warm Period until 900 CE. In both of the chronological schemes, there is a one- to two-century transitional phase between the cold and warm periods.

The Dark Age Cold Period roughly coincides with what is called late antiquity (ca. 200–650 CE) in the Mediterranean and China and with the Late Pre-Classic and Early Classic (ca. 1–500 CE) period in Mesoamerica and the Andes. The Dark Age Cold Period witnessed contrasts in the experiences of civilizations: in the Mediterranean and China, the collapse of the Han dynasty and the fall of the western Roman empire,

while India saw the florescence of the Gupta civilization. During the Dark Age period of cold and moist climate, cities in both Mesoamerica and the Andes prospered, and civilization flowered.

During the Dark Age Cold Period, most of North America and Eurasia were colder and wetter than in the present or during the Medieval Warm Period. Water levels around Lake Titicaca were higher, allowing Tiwanaku crops and culture to flourish. This climate regime also prevailed in Mesoamerica, where Teotihuacan became the metropolis, and the Maya cities began their Classic Period.

But in the Roman empire and China, the cold had serious negative effects. In both northern China and the European provinces of the Roman empire, many rural villages were abandoned, the area under cultivation was diminished, and the rural populations declined seriously. So-called barbarian tribes crossed the Rhine River on the ice in the very cold winter of 406. The barbarians pillaged and eventually destroyed the western Roman empire. This was a marked consequence of the Dark Age Cold Period, but the destructive nature of this adverse climate regime continued.

The Event of 536 caused an abrupt additional cooling of the earth's atmosphere in 536 and the years immediately following, compounding the misery already visited on humanity by the cold cycle. Crop failures, famines, and epidemic disease followed the excessive cold. The Justinian Plague, a pandemic that swept the Eastern Hemisphere in the middle decades of the sixth century, acted with the contemporary famines to reduce populations by 30–50 percent.

In the mid-seventh century, the Dark Age cold began to moderate somewhat. By the ninth century, the warming of the earth's atmosphere accelerated, and the Medieval Warm Period began. The Medieval Warm Period lasted nearly half a millennium (800–1300 CE) and was the longest period of warm climate in the Late Holocene, the last 5,000 years. During this period, glaciers retreated in all of the world's mountains; summers were long, and weather was predictably mild throughout the temperate zones. During this period, much of Eurasia witnessed abundant crops and little hunger year after year. Villages were established on newly cleared fields, and growing populations basked in what they believed was special divine grace.

In contrast, in western North America, in Mesoamerica as well as in the Andes, the centuries from 900 to 1200 were centuries of savage droughts and aridity. The glaciers in the Andes that fed Lake Titicaca and the streams, which irrigated the fields of the Andean civilizations, withered. Crop failures, famines, and the decline of Andean populations were the result. Droughts in Mesoamerica had similar

but perhaps more disastrous results among the Maya lands, where many cities were abandoned and the Classic Period ended.

During the 700 years of this era, the world's population, which had reached a relatively high plateau in the first two centuries CE, declined

The glaciers in the Andes that fed Lake Titicaca and the streams, which irrigated the fields of the Andean civilizations, withered. Crop failures, famines, and the decline of Andean populations were the result.

slightly by 400 CE and then more precipitously until the seventh century. From a low point in the early seventh century, the world's population climbed rapidly to new heights in the ninth century, when it again leveled off, declining sharply in the Americas but rising in the Mediterranean region and India. Below is a tentative chronology of world population rises and falls during this period:

200 CE	World population 240 million
400 CE	World population 200 million
600 CE	World population 180 million
850 CE	World population 320 million
1000 CE	World population 320 million

This estimate masks some very serious population rises and crashes in Europe, China, and the Americas. Since the population was sometimes rising rapidly in one region, a population crash in another region would not be apparent in the total estimate. Throughout these 700 years, a quarter of the world's people lived in China, another quarter in Europe and the Mediterranean region, and perhaps a fifth in India, while the remaining 30 percent dwelt in the rest of the habitable world.

China and the Roman empire both reached a high point of prosperity in the second century CE, when their populations were approximately 60 million each. In the third century the Han dynasty fell, and warfare between the successor kingdoms swept through the land. At the same time, civil wars convulsed the Roman empire. In both places, populations declined, perhaps more precipitously in China than in the Roman empire. While populations were sinking in China and the Mediterranean world, they were rising in India and the Americas. The golden age of Gupta India, the Age of Southernization, when northern India led the world in prosperity and economic development, occurred in the first half of the first millennium. The population rises of India during that period, although not equaling the population crashes of both China and the Mediterranean area during 400–600, were substantial and did mask the China/Mediterranean declines. Meanwhile, populations in Japan, Mesoamerica, and the Andes began to grow relatively rapidly, further masking the declines in China and the Mediterranean region.

With the stability ensured by establishment of the Tang dynasty (618) the population of China again began to rise, to be joined in its upward trend by the population of Europe and the Mediterranean Basin after 700 CE as well as southern India and the Americas. The upward trend peaked at about 320 million in 850. While populations in Europe, Southeast Asia, and Africa south of the Sahara continued to rise after 850, China's population responded to political instability and natural disasters by a sharp decline from its high point of 80 million.

Almost as numerically significant as China's population loss was the demographic disaster that struck Mesoamerica and the Andean civilizations as a consequence of drought and environmental degradation in the ninth and tenth centuries. The population of Mesoamerica and the Andes, by some estimates 28 million in 850, crashed by 80 percent, to less than 7 million in the tenth century. The Maya population alone declined

from a high point of 12 million to little more than 1 million in a few generations. Thus, in the seven centuries of this era, world population increased perhaps 80 million, but this was not a smooth and steady increase. Instead, the trajectory of population increase was something like a roller coaster.

During these seven centuries, the world's people were very unevenly distributed over the normally habitable regions. People were densely clustered in small tracts of fertile or easy-to-work soil so that inhabited areas resembled islands of population, separated by large sparsely inhabited areas. The floodplains of major rivers, such as the Yellow River, the Yangtze, the Ganges, the Indus, the Tigris-Euphrates, and the Nile, were still the homes of a large part, perhaps half or more, of the earth's people, but other smaller areas of high fertility were also important.

Outside the densely populated river valley floodplains, the areas of dense population became smaller. People still congregated in relatively congested villages, but large tracts of forest or other scantily inhabited wasteland, where bandits often lurked and pastoral peoples dwelt, separated the villages.

In northern China, the Loess plateau with its very fertile soil had been thickly settled since about 500 BCE because the Chinese had developed a special type of iron plow to turn the soil. Indeed, one of the reasons that China, as early as the beginning of the Common Era, had the most dense and sometimes the best-fed population in the world—the reason that China was home to a quarter of the world's population—was that the Chinese had developed a superior system of agricultural technology. This involved highly developed hydrological management for both flood control and irrigation, the extensive use of iron tools, a high investment of labor in intensive cultivation, and a broad but carefully developed variety of crops including rice, wheat, millet, soybeans, and the like.

The Ganges Valley was another very fertile and densely populated area. Here, the soil was easily worked, and the land was extremely fertile, so fertile that it was possible to plant the same crop year after year without the necessity of leaving the land fallow. It was customary for farmers in this area to harvest two and often three crops a year: rice in

In Southeast Asia, the majority of the people inhabited the floodplains of the river valleys where wet-rice farming supported large villages. Here, as in India, large tanks were constructed to irrigate the winter crops.

the summer monsoon season and wheat in the drier winter season. Often varieties of beans were also harvested. In some locales along the Ganges, sugarcane and cotton were also raised. During the first half of the first millennium CE, the villagers were also beginning to clear the forests in the Punjab and to the south of the Ganges Valley, making heavy use of iron

tools. To permit cropping of the fields during the winter dry season, the people of India built reservoirs, or tanks, to store water from the summer monsoons.

In Southeast Asia, the majority of the people inhabited the floodplains of the river valleys where wet-rice farming supported large vil-

lages. Here, as in India, large tanks were constructed to irrigate the winter crops.

From the eighth century on, an ever-denser population harvested multiple annual rice crops on the rich volcanic soil of Java's Kedu Plain. In a broad zone stretching from the Tarim Basin in central Asia to the Atlantic shore of North Africa, including Iran, Mesopotamia, Syria and Palestine, Arabia, Egypt, and Mediterranean Africa, where the principal crops were wheat, barley, and similar grains, agriculture and civilization were possible only because people made copious investments in irrigation: in digging and cleaning wells and in building and maintaining dams, canals, or, in Iran, underground water tunnels (*qanats*).

In southern Arabia, the Himyarite civilization flourished on the agriculture made possible by the 1,000-year-old Marib dam. It was a catastrophe of epic proportions when the Marib dam collapsed in the late sixth century. The dam was never rebuilt. Famine and a vast out-migration of destitute South Arabian refugees ensued.

In the Mediterranean Basin, the winters are cool and moist, while the summers are hot and dry. Here, grain crops, chiefly wheat, were grown in the winter, with wine grapes, olives, pistachios, and other tree crops harvested in the summer. Livestock, principally sheep and goats, fed on increasingly overgrazed hillsides. This region did not support the dense populations that the wet-rice areas of Asia did, but because the land north of the Mediterranean consists of four peninsulas (Anatolia, the Balkans, Italy, and Spain), the population often could supplement their diets with fish and other seafood.

Northern Europe had a denser forest cover than the Mediterranean region. At the beginning of this era, during the Dark Age Cold Period (200–700), population declined, gradually at first but precipitously during the demographic turmoil resulting from the Great Migrations of Germans and Slavs (400–800). Villages were deserted, the area under cultivation was diminished, and forests expanded.

With the lengthening growing seasons during the Medieval Warm Period (800–1300), North European peasants founded new villages, cleared more forests, and put new fields under the plow. Vineyards, which had been absent from the British Isles since the second century, flourished in southern England, and wheat could be grown in southern Scandinavia where only rye could be grown during the Dark Age Cold Period. New technology was necessary to cultivate the heavy forest soils of northern Europe, and it was early in the Medieval Warm Period that European farm folk adopted iron-wheeled plows and load-pulling horse collars, developed in China centuries earlier.

The climate in Africa south of the Sahara probably did not change as much as that in Europe or Asia, but the African population changed significantly during this period. Asian crops, which had been introduced to East African ports early in the Common Era, diffused across the continent in the first millennium CE. These Asian crops, including Asian rice, taro, sugarcane, and, most important, bananas, stimulated a remarkable population increase throughout Africa south of the Sahara.

The Bantu, whose 1,000-year expansion from West Africa reached its limit in East and southern Africa in the early centuries CE, adopted

the grain-raising and cattle-herding practices of the Cushite and Nilo-Saharan peoples with whom they intermixed and, in doing so, changed some of the East and southern African forests to open savanna.

In the Americas, the moister and cooler climate regime of the first half of the first millennium CE allowed the high civilizations of Mesoamerica and the Andes to flourish. This was the Classic Period of the Tiwanaku, Wari, Nazca, and Moche civilizations in South America as well as of the Maya, Zapotec, Teotihuacan, and other civilizations in Mesoamerica. But a 30-year drought struck both areas in the mid-sixth century, and a phenomenal El Niño seriously damaged Moche and other coastal Andean civilizations in the eighth century. Finally, in the ninth and tenth centuries these regions suffered a 300-year-long series of droughts that caused these Classic Period Andean and Mesoamerican civilizations to collapse.

However, until their collapse, these civilizations each developed sophisticated systems of water management to maximize food production. In Tiwanaku, this involved the construction of extensive raised beds in the wetlands surrounding Lake Titicaca to both provide dry soil and warm the microclimate of the raised beds in order to produce bountiful crops of potatoes. The Wari and Moche constructed elaborate irrigation canals and mountain terraces. The Maya and other Mesoamericans used an elaborate system of irrigation canals, terraces, and raised beds.

All of these systems proved very efficacious in the relatively moist times, but when the centuries of drought set in, not even the most elaborate water management systems served to ward off disaster. Human-caused environmental degradation compounded the calamity of the great drought. In their centuries of glory, the Mesoamericans as well as the Andean civilizations were prodigal users of wood for fuel and for construction timbers and to make fired bricks as well as lime for plaster from limestone. After nine centuries of forest cutting, the land was denuded. When the dry years came and the wind swept through the Mayan cities, the unprotected land became a dustbowl. Famine and the population, which had reached an estimated 12 million, plummeted to perhaps a tenth of that.

Deforestation was an omnipresent problem wherever agriculture expanded and populations grew. Everywhere, humans used wood for fuel; for constructing temples, palaces, and common dwellings; for shipbuilding; to fire pottery kilns; and in furnaces to smelt the iron tools and weapons that complex civilizations required in ever increasing quantities. In northern China by the tenth century, deforestation was so severe that iron makers were forced to use coal instead of charcoal. This was a very expensive process and produced inferior iron until Chinese metallurgists discovered the method of purifying the coal by using destructive distillation to drive off the sulfurous gasses and make coke.

By the fifth century, deforestation had reached serious proportions in the lands around the Mediterranean Sea. The Roman empire, with its vast construction projects, used wood and timber on a lavish scale. The

Romans used prodigious quantities of cement, which they made by baking limestone in kilns. Much of the forests in Greece, Italy, Spain, North Africa, Anatolia, and Syria were gone by the fifth century. Where the forests on the mountainsides were cleared, sheep and goats grazed, eating the shoots of new tree seedlings. Lands that had been covered by lush forests had now become permanent scrub.

In northern Europe, deforestation proceeded at a much slower pace. The army, in building defensive fortifications, particularly Hadrian's Wall in northern Britain, its roads, the bridges across the Rhine and the Danube, and the military camps, cleared a wide swath of forest along the frontier, but this became naturally reforested after the fall of the Roman empire.

More ecological change during the first millennium involved the extinction of several species of mammals, birds, and reptiles. In North Africa, the last of the wild elephants as well as lions and other species, prized for their use in Roman arenas such as the Coliseum, were hunted into extinction. In West Asia and Iran lions disappeared, as did elephants, rhinoceroses, and tigers in southern China.

The Malagasy settlers of Madagascar exterminated several species of lemurs, pygmy hippopotami, a crocodile unique to the island, and the giant roc, a huge flightless bird.

The Polynesians, in settling the Hawaiian Islands, destroyed habitat and inadvertently drove several unique species to extinction. The early Hawaiians, before they harvested their first crops, supported themselves by hunting to extermination the Hawaiian flightless goose. Early settlers in other parts of eastern Polynesia caused similar exterminations. Other human-generated exterminations, particularly of plants, are likely to have occurred during this period.

In the early medieval age, most sedentary populations lived in relatively large peasant villages, though a small but important minority lived in cities. Throughout most of the globe, the urban population comprised less than 5 percent of the total population, and most cities, by modern standards, were very small, with less than 10,000 inhabitants.

These small cities had a modest impact on the local environments, although there was usually deforestation in their immediate vicinities. It was the few giant capitals that had the largest environmental impacts. Rome, Chang'an, Baghdad, Constantinople, and Teotihuacan all imposed major demands on their environments. Rome's demands for potable water required the construction of an elaborate system of aqueducts to bring in water from distant sources. In China, feeding the huge population of Chang'an, capital of the Tang dynasty, required the building of the 1,500-mile-long Grand Canal, the world's longest artificial water channel. On this canal, myriad canal boats, laden with rice and other foods, daily transported their cargos from the distant fields in the Yangzi Valley to feed the mighty capital.

In North Africa, the last of the wild elephants as well as lions and other species, prized for their use in Roman arenas such as the Coliseum, were hunted into extinction. In West Asia and Iran lions disappeared, as did elephants, rhinoceroses, and tigers in southern China.

Teotihuacan, the Mesoamerican metropolis, posed difficult problems. The city's population is estimated at 150,000 to 300,000. The city was landlocked, and because the Mesoamericans had neither wheeled vehicles nor draft animals, all food, fuel, timbers, obsidian, and other necessities were brought in by human porters. Within a few centuries, the area around the great city had been stripped of forest. Fuel and timber became very expensive, but that was not an impossible problem. When a long period of drought in the second half of the sixth century ruined crops in the Teotihuacan area, it proved impossible to feed the citizens from distant sources using human porters. Famine set in, and the destruction of the city by the desperate residents followed.

Even though the later part of the first millennium witnessed the destruction of cities and the collapse of civilizations in the Americas, in Africa and Eurasia the favorable climatic conditions allowed populations to grow, cities to develop, and new states to emerge. This resulted in an even greater human footprint on the planet.

■ Introduction: Environmental Events

Although detailed information of environmental events during this period is not as abundant as for more recent ages, nevertheless a picture (admittedly very tentative) emerges. Many paleoclimatologists (scholars who study ancient climates) sketch a climate chronology for the first millennium CE that begins with a warm period that lasted to about 300 to 400 CE, followed by the Dark Age Cold Period, which may have continued until 700 CE, and then the Medieval Warm Period, which lasted for five centuries (800–1300 CE). This chronology is based mostly on the study of ice cores from the Greenland and Antarctic ice caps as well as dendrochronology (the study of ancient growth rings in trees) in many locations.

Patterns of climatic events were sometimes similar in the Americas and the Eastern Hemisphere, but often they were at wide variance. The Dark Age Cold Period brought massive social disruption and suffering to parts of Eurasia at a time when the civilizations of Mesoamerica and the Andes were approaching the glory of their Classic Period, and whereas the Medieval Warm Period brought five centuries of agricultural expansion and prosperity to most of the

temperate regions of Eurasia, it had a different effect in western North America, much of Mesoamerica, and the Andes. During the last centuries of this period (300–1000 CE), these areas suffered serious and long-lasting droughts, which caused the collapse of civilizations in the western parts of North and South America as well as much of Mesoamerica.

Adding to this picture is the record of the El Niño–Southern Oscillation, the changes in surface temperature in the western and eastern tropical Pacific Ocean. These changes, which are believed to occur at intervals of three to eight years, can cause damaging torrential rains in some regions, especially the west coast of South America, and debilitating droughts in other regions, such as the normally drenched rain forests of Indonesia. According to some archaeologists, a super El Niño caused a gigantic flood that destroyed Moche, a city on the coast of Peru, in about 700 CE.

Other less-recurrent events also had a major environmental impact. Scholars argue about the nature and causes of the Event of 536, the consequences of which included widespread crop failures, famines, and extreme cold weather.

—Wilfred J. Bisson

El Niño Events

The global events of El Niño and the Southern Oscillation (ENSO) are two related climate patterns that recur very frequently. ENSOs primarily affect the Pacific Ocean and the Indian Ocean. Every two to ten years, atmospheric and oceanic temperature patterns change. This drastically alters the climate and weather of India, North and South America, and Asia. Although there is no clear evidence of the dates of ENSO events between 300 and 1000, they did occur, often with catastrophic results.

El Niño was named for the Christ-child by Peruvian fishermen because of the event's irregular appearance around Christmastime. The effects of the ENSO have long been noted, but the cause of this enormously influential weather pattern was not widely understood until the 1970s. El Niño is triggered by a decrease of the Northeast trade winds and a reversal of the air pattern called the Southern Oscillation. This pattern disrupts the monsoonal rains in Southeast Asia. Monsoons occur annually between June and September, and most agriculture depends on the rains. ENSOs can cause crippling droughts throughout the area. Such droughts are very hard to trace in historic records from 300–1000, but science can reconstruct the patterns of ENSO events.

Although not every ENSO causes catastrophe in human societies, some extreme events have been linked to famines across the world. The global effect of ENSO can be seen in the fact that scientists have used data about the annual flooding of the Nile to find out when ENSOs happened in the past. Scientists have identified ENSOs from 622 to 1522 CE.

ENSO also affects the other side of the globe; by December, as the warmer waters move to the coast of South America, there is a rise in rainfall. Yet by dumping rain sooner, ENSO could even cause droughts in other areas. In coastal South America, ENSO causes flooding and the destruction of crops and irrigation networks. The warm waters also hurt fish populations, and societies dependent on fishing have been badly hurt by the disappearance of fish.

ENSOs happen very frequently, and societies in affected areas developed ways to cope with the patterns. Yet particularly bad series of his-

THE COLLAPSE OF THE MOCHE

The Moche society in ancient Peru began around 1 CE. Suddenly, after 700 CE, the Moche society collapsed. The Moche lands were drought-prone, so their agriculture was based on irrigation networks and fishing. Recently, scholars have suggested that the collapse was linked to extreme environmental catastrophes, including desertification and earthquakes. There were also extreme ENSOs in 600, 612, 650, and 681 CE. These would have caused severe floods, destroyed the irrigation systems, flooded out crops, and devastated Moche fishing. Although ENSOs cannot be said to have directly caused the collapse of the Moche, they definitely contributed to it.

—Ellen Arnold

toric ENSOs may be partially to blame for large crises in different societies. During the seventh century CE, a series of ENSOs may have been linked to the end of Moche society in Peru. Another series of ENSO-related droughts may have contributed to major problems for the Maya in the Yucatan Peninsula. Around 900 CE many Mayan temples, cities, and settlements were suddenly abandoned in the middle of political chaos. Although all of the reasons for this Classic Maya Collapse will never be known, a decades-long drought in the ninth century, likely triggered by ENSO, contributed. The population decline in the Yucatan became, in a way, its own environmental event. As the agricultural system collapsed, the landscape that had been altered by the human presence gradually returned to jungle.

Problems in Early Medieval Environmental History

There are two basic questions that historians face when dealing with the history of world climate. The first is, what happened to the climate? The second question, at points even more difficult to answer, is, what effect might climate have had on human societies? For the period 300–1000 CE we are just beginning to have answers to these questions.

In order to understand the history of climate and environmental events, climatologists, environmental scientists, archaeologists, and historians have to combine their sources. From the historical perspective, for the period ca. 300–1000 CE there is much less written data to work with than at other times in world history. We have to rely heavily on archaeological evidence and scientific data. Scientists gather and compile what is known as proxy data, which includes evidence from tree rings, ice-core samples, pollen counts, and surveys of ocean floors and changing coastlines. Advances in technology and better abilities to compile and compare results are making this evidence better by the year. Ironically, these improvements are making it harder to make bold statements about the history of climate change.

The best example of this is the era known as the Medieval Warm Period. Beginning in the 1960s, many scholars argued that there was evidence of a substantial warming of the Northern Hemisphere between circa 900 and circa 1400 CE. However, there are many recent challenges to this idea, in part because there is little solid evidence for corresponding changes in the Southern Hemisphere’s climate. Also, widely different regional changes are being noticed, and scientists point out that broad generalizations about warming or cooling are not possible. For example, some evidence suggests that Scandinavia became warmer as early as 600 CE. In parts of North America a warmer period began in 700

CE, but Alaska was warmer during 500–800 than in the following centuries, contrary to the generalized Medieval Warm Period.

This variability in the data at both regional and temporal levels makes the era of 300–1000 difficult to assess. After circa 1000 CE, proxy and historical data become more precise and easier to use. Better sources, an interest in the Medieval Warm Period, and a concern to identify the results of industrialization all contribute to the fact that there are many more attempts to understand the 1,000 years after 1000 CE than those before.

Finally, there is a gap between events that we know about and our ability to understand their effects. Often we know that a society suddenly thrived or failed, but we do not have a clear sense of a specific political, social, or environmental cause. At other times, there is clear proxy evidence for a significant natural event or a climate fluctuation, but because of a lack of written evidence or archaeological investigation, it is almost impossible to understand the impact of this event.

Yet in spite of these challenges posed by evidence, methods, and even the goals and interests of scholars, there are some things that can be better understood about the impact of climate between 300 and 1000 CE. There are several types of events or change that have been traced and identified, including single unusual events with wide ramifications. A clear example of this is the 536 event. This event was associated with short- and long-term climate change and astronomical phenomena throughout the Northern Hemisphere. Because of its severity, people took notice, and it is an example of a natural phenomenon that can be traced in proxy data and in historic sources.

Another category of climate or environmental events is the ones that are, on an individual basis, unpredictable yet are routine enough that scientists know better how to look for them in the proxy data. Such events include earthquakes, volcanoes, and tsunamis, events often thought of as natural disasters. Unfortunately, because they are more routine, often they were not noted or elaborated on in historical records. These are increasingly recoverable via scientific investigation, the results of which can be compared to

archival and historical records. Yet scientific objectives in researching past climate do not always overlap either historians' questions or methods. In addition to the biases of scientific inquiry, there are also problems in the historic record that need to be addressed.

As historians working on natural disasters and epidemic disease have shown, culture and society are also a part of the process through which a disaster is created. Nature's processes can be exaggerated or altered by human intervention, and human settlement patterns and agricultural and political organization can shift a natural event into the realm of disaster. It is at that point, of course, that we are more likely to find traces in the human record. For example, though it is now known that Mount Vesuvius may have erupted 13 times between 300 and 1000, most of these eruptions were unrecorded or unreported in the historical record. Because of its disastrous impact, the famous 79 CE eruption was far better documented and thus becomes a bigger event in our modern imaginations as well.

Finally, there are recurring events, such as El Niño, monsoons, typhoons, and other shorter-term climate patterns. Because their causes and effects are well known, such events are sometimes easier to trace than single events. For example, because we understand the global effects of El Niño, regular notations that were made of the Nile flood can now be combined with proxy data from the Americas to trace the El Niño cycle between 300 and 1000 CE. But it is difficult to establish the exact results of any single El Niño event. Because shorter-term changes in rainfall were often routine, many societies adapted their agricultural patterns to them, and it is harder to determine their effects on societies.

In the entries on climate events that follow, there is discussion of the possible effect of environmental events. But it should be remembered that such results are perhaps even more difficult to determine than global climate patterns. In the evolution of human societies, economy, religion, politics, and culture change things at the same time that natural events are occurring. Untangling the web of causes and effects is the great challenge for those seeking to understand the role of climate in human events.

The Beginning of the Medieval Warm Period

From 800 to 1300 CE, a time known as the Medieval Warm Period (MWP), the earth's average climate warmed several degrees, and ecological zones moved several hundreds of miles northward in the Northern Hemisphere. The highest temperatures during this period were the century and a half from 950 to 1100 CE. Various theories of causation for the MWP have been suggested, but it is often partly attributed to a spike in solar energy known as the Medieval Solar Activity Maximum. Paleoclimatologists cite evidence from samples taken from the Greenland and Antarctic ice cores as well as the testimony of growth rings in ancient trees that support the claim of higher temperatures during the MWP. Isotope analysis of the gases trapped in Greenland and Antarctic ice cores supports the concept of the Medieval Solar Activity Maximum.

During the half millennium of the MWP, glaciers in the Alps, the Andes, the mountains of East Africa, and the Himalayas retreated. Hardwood forests, especially beech and oak, migrated to more northerly latitudes, and agriculture followed.

Crops such as wheat, rye, maize, beans, and grapes, which had been domesticated in regions with warm climates, were successfully grown in more temperate regions. For example, grapes, which during the centuries before 700 CE had been unknown in northern Europe, were by 800 CE harvested in England, southern Germany, and Hungary. During the MWP it was not necessary for the Catholic Church to import expensive sacramental wine from southern Europe. Wheat

THE CONTINUING CONTROVERSY

The concepts of the Little Ice Age and the Medieval Warm Period emerged in the 1970s when meteorological scientists, particularly Hubert Lamb of the British meteorological office, discerned these patterns from studying medieval literature and modern records.

While the idea of the Little Ice Age was readily accepted, the concept of the Medieval Warm Period was, for a time, subject to widespread skepticism. In the face of mounting evidence, much of the skepticism dissipated. Those who deny that human activity promotes global warming seized on the concept of the Medieval Warm Period to support their contention that the present global warming is a natural cyclical phenomenon rather than an anthropogenic (human-caused) event. Supporters of the idea of anthropogenic global warming maintain that the present rate of global warming is much faster than the natural warming cycle would cause.

While controversy over the existence of the Medieval Warm Period persists, a consensus of climate scientists now accept it, although some still question whether it was a global or regional phenomenon, but investigators are finding evidence of it in almost every part of the world. Disagreement continues, however, as to the height of the average temperature during the Medieval Warm Period maximum. Did the average temperature during Medieval Warm Period maximum, which lasted for a century and a half, reach or surpass those of today? Or are today's averages warmer?

—Wilfred J. Bisson

replaced rye as the staff of life in much of northern Europe, while rye fed even more northerly populations. Wet-rice farming moved into more northern areas in China, Korea, and Japan, while maize, beans, and squash, the so-called three sisters of Mesoamerican agriculture, were adapted for cultivation by the Pueblo peoples of the North American Southwest and the Mound Builders of the Mississippi Valley and the North American southern woodlands.

The disappearance of ice floes in the North Sea and the Baltic Sea resulted in an upsurge in pelagic fishing. A consequence of the northward

march of farming and ocean fishing was a significant increase in food production. This along with more consistency in the climate resulted in larger and better-fed populations. The decimation of populations by periodic famines was, for these centuries, held in abeyance. People probably enjoyed longer lives and saw more of their progeny live to adulthood.

As agriculture and population spread north, new cities emerged, and new villages were planted in the now dense forest. In Europe, this meant a move into previously sparsely settled lands and the creation of Newtowns, Newburgs, and Novgorods. West Europeans moved into the wilds of Slavic eastern Europe, a movement that Germans call *Drang Nach Osten*, and Japanese occupied the northern reaches of the island of Honshu. Not only did new agricultural settlements and cities appear, but also new states and chieftainships emerged in what had been northern wilderness. In Europe these included the Scandinavian kingdoms, Poland, Bohemia, and Kievan Rus, while in northeastern China (Manchuria), Parhae appeared. In North America, the Pueblo peoples formed chieftainships in the Southwest and the Mound Builders did so in the Southeast. The retreat of glaciers in the Himalayas and the spread of barley farming were probably factors in the flourishing of the empire of Tibet.

Viking voyages to and establishment of settlements in Iceland, Greenland, and North America were possible because of the retreat of sea ice in the North Atlantic, while the presumably calmer seas during the MWP facilitated the great burst of Polynesian navigation in the Pacific Ocean during this time.

The MWP started in the early medieval age and continued well into the high medieval age, but global climates cooled in the early fourteenth century CE. At that time, the much colder Little Ice Age began and persisted until the mid-nineteenth century. Because of the increase in sea ice, the Norse settlements in Greenland died. Alpine glaciers once more expanded, and some mountain villages were abandoned. But for the most part, the northerly march of agriculture and settlements that had taken place during the MWP was not reversed. These northern villages and cities suffered, but although there may have been some decline in population, the remaining

people adapted to the harsher climate. Most of the expansions in area of settlement were permanent, persisting through the Little Ice Age to the present era of global warming.

First-Millennium Droughts

There were many droughts between 300 and 1000 CE. Each of these could be catastrophic to individual communities and to the human, plant, and animal inhabitants of entire regions. Most droughts from this era will never be known, but some are known because they were great enough that they left a record in human and natural archives. Droughts were caused by long-term events such as climate change or the El Niño and the Southern Oscillation (ENSO) cycles. Droughts were also caused by sudden events such as volcanic eruptions.

For example, the strange event of 536 CE led to cold weather, drought, and famine throughout the world. In southern China, extraordinarily cold temperatures led to crop failure and unimaginable losses. One administrative record suggests that in a particularly hard-hit region, 70 to 80 percent of the people died of starvation. Such numbers may be exaggerations, but when combined with other stories and sources, the impact of the cold and drought is clear. This drought was also hard on the nomadic steppe groups of northern China. The loss of good pasture may have triggered some of the nomadic groups to move west. The broad impact of such events is that as the nomads moved west, they fought for limited resources with Roman populations in eastern Europe.

An example of droughts caused by climate trends is a series of droughts in North America that lasted from 450 to 1300 CE, when the Americas became colder and drier. In the California area, the most severe droughts took place during 500–800 CE, and another bad period began

around 950 CE. Ice caps records from the Andes show that South America had dry periods during 540–610 and 650–760 CE, and lakes in the Yucatan Peninsula record droughts in 860 and 922 CE. Studies of a marsh in New York suggest that a 500-year-long drought began around 800 CE.

The Chumash people on the coast of California suffered from droughts beginning around 450 CE. Although the cold weather and droughts were very destructive to agriculture and plant life, fish populations off the coast were helped by colder waters. Coastal communities were harmed less because they relied on fishing. But areas that relied on grazing, hunting, and gathering were badly affected. Over time, these droughts became worse and may have contributed to war and conflict within Chumash society. Single environmental events could have very different effects within the same region.

In India, many sources record droughts between 300–1000. (One author described a drought around 700 CE that lasted for 12 years.) Agriculture in India relied almost entirely on monsoon rains; if they did not come or were too small, famine could occur in the whole subcontinent. The history of drought in India can be traced by historical ENSO patterns and in Nile River levels because low levels in the Nile are linked to drought in India. During 600–1000 the river was lower than usual more than 100 times and was especially low in 683–696 and 770–782.

➤ THE COLLAPSE OF THE MAYA

Maya civilization flourished in the Yucatan during 200–800 CE. One of the signs of their success was their ability to adapt their agriculture and technology to their environment. Yet by 900 CE, Mayan lowland civilization unexpectedly collapsed. This collapse may have been linked to droughts. Between 750 and 1025 CE, droughts plagued Central America. Venezuela suffered from droughts in 760, 810, 860, and 910. The drought from 910 may have lasted for six years. Although also connected to economic, military, and social patterns and changes, the Maya collapse happened during a period of drought that harmed the region's agriculture.

—Ellen Arnold

Droughts in India, like droughts in the Americas, could be part of global climate patterns.

The Event of 536—Problems in Understanding Environmental Events during 300–1000 CE

Environmental changes can have a profound impact on human life. Around 536 CE a severe and as of yet unexplained atmospheric event, generally known as a dry fog or a dust-veil event, triggered intermediate and long-term climate changes throughout the Northern Hemisphere. Writers from Byzantium, Rome, Ireland, and China described strange sights in the skies, cold winters, and famines. Some scientists have suggested that the conditions were caused by a massive volcanic eruption that spewed gas and particles into the atmosphere. There have also been suggestions that a meteorite or a comet caused the event.

Written reports of the event are substantiated by comparing many series of sixth-century climate data from around the world. It first showed up in ice core analysis from glaciers. Some of the ice core samples from around 540 CE (plus or minus ten years) show a layer of high acidity and dust similar to that found when large volcanoes erupt. The study of tree rings (dendrochronology) shows a major event in the years 536–545 CE. Something caused shockingly low growth rates in trees in North America, Ireland, continental Europe, and Scandinavia.

Thus, the dust veil appears to have blocked much of the solar radiation, cooling the climate and hurting plant growth. Indeed, after 536 there were crop failures and famines as far apart as China and Ireland. In addition to short-term effects, this dust veil may have triggered dozens if

not hundreds of years of cooler weather. To understand whether or not this was an event of global importance, scholars have begun to compare mid-sixth-century economic, social, and political events from across the world. Historians and archaeologists have explored how the event might have been linked with the fall of Rome, the Maya hiatus, dynastic troubles in China, and problems in two African civilizations.

Written sources that describe the 536 event are not numerous or detailed, but they are tantalizing evidence that the event was big and was associated with the atmosphere. A Roman politician, Cassiodorus, reported that for an entire year, something unusual and mysterious happened in the sky, muffling the sun and moon. He, like many people during the age, equated such unusual events with a sign from God but still feared that crops would continue to fail and that normal weather would not return. Zacharias of Mythlene reported that for seven years the stars behaved strangely, and Chinese sources note famine, comets, and that the star Canopus could not be seen in the sky.

The 536 CE event shows the importance of paleoclimatology (the scientific study of past climates) in world history. Scientists have shown that this event was global in its scope. But this event is also a reminder that the causes and results of past major climate events are often veiled in uncertainty. There is no consensus on what caused the 536 event or what its impact was. The sixth century CE is a period for which there are often few written sources, which makes it even harder to understand its effects and to separate problems caused by the event from problems that had already begun.

The Early Medieval European Environment

Before the Industrial Revolution was well under way in the nineteenth century, at a time when most people in the world were directly or indirectly engaged in agriculture, changes in climate had a profound impact on human lives. In the European world, several periods of significant change are now well recognized: the Medieval Warm Period (approximately 800–1300), which corresponded to a long wave of population growth; the first wave of the Little Ice Age (whose onset was announced by the great European famine of 1315–1322); and the second wave of lower temperatures during the long seventeenth century. The extent to which these climatic phases in Europe corresponded to equivalent (or opposite) phases in other parts of the world—for example, the extended drought in the southwestern regions of North America during the European warm period of the eleventh and twelfth centuries—remains a hotly debated question. The colder and wetter climatic phase of the mid-first millennium CE (the early Middle Ages) must be added to this list, as it is essential to understanding many of the important changes in agriculture, settlement patterns, and the shape of the landscape itself between the fifth century and the beginning of the great medieval demographic and economic expansion in the tenth century.

As used here, the term “climate” is not the same as “weather.” Weather is what we experience from day to day: today is warmer or colder than yesterday. Climate is described by the average temperature and precipitation over the long term. That long term may be calculated over periods of time from tens of decades or centuries to tens of millennia or millions of years. For historians, multidecadal to century-long changes are the most interesting. As recent studies of the consequences of global warming have shown, plants and animals respond to such changes (for example, their geographic range may shift, or their time of flowering or breeding may change). As a consequence, agricultural crops may fail more frequently, or diseases may spread among domestic animals. And these events will present serious challenges to which society must respond.

➤ AGRICULTURE AND FORESTS

It is often imagined that the Romans were responsible for opening up the landscape in the lands they conquered and using it for agricultural production and that the lands beyond the Roman frontier were largely impenetrable forest. Neither of these is true. Pollen studies show that the great wave of land clearance for agriculture began in the late Bronze Age (starting around 2300 BCE). Roman-era farmers moved into lands long since cleared. The development of cities during the Graeco-Roman period gradually connected agriculture to the commercial circuits that fed those cities. With the decline of cities in the west, beginning in the third century CE, those circuits gradually vanished. Population fell in the countryside as well as in the cities. In what had been the Roman world, agriculture switched from a primary emphasis on grain production and stock raising for urban consumers to a primary emphasis on pastoralism, supplemented by grain for household consumption. Agricultural land was abandoned and slowly reverted to forests. These would only be cleared again in the eleventh and twelfth centuries.

—Fredric L. Cheyette

Climates differ from region to region. Europe has three large climatic regions: Atlantic, Continental, and Mediterranean. The boundaries between these regions shift from season to season, but the general seasonal geographic pattern appears to have remained relatively stable over the last two millennia. Within these regions, studies based on instrument records since the mid-nineteenth century have shown that temperatures at sites quite distant from each other move up and down at approximately the same time; on the other hand, sites near each other may show quite different patterns of precipitation. This complicates any attempt to generalize climate data from particular sites to large regions or all of Europe.

Instrumental records of temperature and precipitation begin, for the most part, in the mid-nineteenth century, though a few go back to the mid-eighteenth century. For information before that time, historical climatologists are dependent on proxy records, that is, noninstrumental

records that can be linked to changes in climate. These may be written—records, for example, of the dates of grape harvests—or, most often, physical or biological: changing species of plants in peat bogs reflecting changes in rainfall, records of floods provided by layers of alluvial soil, evidence of glacial growth and shrinkage provided by relict moraines. The evidence for first-millennium climate is necessarily of this sort.

In Europe, a shift toward wetter and colder weather began during the late fifth century and extended into the seventh century. There was a less severe repeat of this phenomenon around the mid-ninth century.

Evidence for greater precipitation in the north comes primarily from studies of bogs and lakes, whose flora and microfauna respond to changes in water levels. Research during the 1980s and 1990s revealed a wet shift between 450 and 600 at 10 of the 21 bogs surveyed in the British Isles. Nine of the 21 showed a repeated wet shift between 800 and 950. The same wet shifts have been found at bogs in Scandinavia and northern Germany. In southern Europe, studies of alluvial soils along the Arno and Po rivers indicate periods of intense flooding between 500 and 700 and again in the ninth century. A lake in the French Alps that was repeatedly flooded by the Rhone River until the late nineteenth century has given the most refined dating in the layers of alluvion laid down on the lake bottom. An analysis of silicates washed down from the mountains showed a steady increase in the size and frequency of floods beginning around 400, reaching a height between 550 and 600 and then tapering off around 800 to return to the levels and frequency of the beginning of the first millennium.

Evidence for temperature changes comes principally from dating the growth and retreat of Alpine glaciers, determined primarily by winter precipitation and summer temperatures. A study of three glaciers (Aletsch, Gorner, and Lower Grindelwald) shows nearly synchronous expansion between 500 and 600 and again between 800 and 900. In the eastern Alps the cooling period and growth of glaciers began a century earlier. In all these areas the glaciers reached or surpassed their length in the mid-nineteenth century at the end of the Little Ice Age.

These changes in climate had profound consequences both in the short term and in the long term. The upsurge in precipitation that caused the most devastating floods in the years around 600 (one in Rome in 589 is mentioned by Bishop Gregory of Tours in his *History of the Franks*) was doubtless responsible for the severe famine in Gaul in 585 (also mentioned by Gregory). The lack of narrative sources from this period prevents us from tabulating these events in any detail.

More significant were the consequences for agriculture and settlement patterns. Over much of western Europe, the heavy clay soils and the river valleys that provided the richest soil for grain were abandoned. In many areas, such as the lower Po Valley, they turned into marshes that would not be drained and put back to agricultural use until the nineteenth or twentieth century. In the Paris basin and elsewhere in the north, the heavy soils would not be worked again in some areas before the eleventh or twelfth century. It was during the sixth and seventh centuries that alluvial soils covered many ancient ports around the northern Mediterranean and moved the shoreline farther out than it had been in antiquity.

The most long-lasting consequence was in the location of rural habitation. River valleys had been favored in the ancient world because of both the richness of their soils and the ease of transportation for their produce that waterways provided. Between the fifth and seventh centuries as these older sites were abandoned, new settlements began to appear at higher elevations, on hillsides or hilltops. Many of these became the nuclei for villages that developed centuries later, many of which remain to the present day.

■ Introduction: Environmental Constraints and Human Adaptation

In very few places on earth are environmental conditions so salubrious that they require no special adaptation for human existence. In the arctic, snow, ice, and cold require special clothing and ways of getting food; in the desert, lack of water and food and the presence of sometimes excessive heat are problems; and on the South American Pacific coast, El Niños can bring excessive rains. In Australia, irregularly recurring killer droughts impose severe constraints to human settlement. The environment almost always imposes limitations or compulsions to which humans must adapt.

In the era of expanding regional civilizations (300-1000), some of the most remarkable adaptations were those of the Dorset and Thule Inuit. The Dorset people preceded the Thule in the North American arctic and were very well adapted to the extreme cold. In the centuries before the Medieval Warm Period (800-1300 CE) the Bering Sea and Arctic Ocean coasts were locked for most of the year in ice. The Dorset people lacked bows and arrows and projectile weapons in general, but they were able to successfully hunt seals by walking on the ice to the seal blowholes. With the onset of the Medieval Warm Period (about 800 CE) the Arctic ice retreated from the coasts except in northern Greenland and a few other high-latitude islands. The Thule people, who were the ancestors of the Inuit, developed seagoing watercraft (umiaks and kayaks) built of driftwood and seal or walrus skin with which to pursue whales on the open ocean. The Thule hunters, with their newly developed toggle harpoons, were adept whale hunters, while the possession of bow and

arrow technology afforded them equal success in hunting land animals, such as the caribou and musk ox.

Inland, in Arctic Eurasia, northern hunters adapted to the Medieval Warm Period by reducing the extent of their nomadism and taming, if not domesticating, reindeer. It has been estimated that reindeer were tamed as draft and riding animals as early as the first century CE, but the practice of using tame reindeer both as draft animals and for milk apparently did not occur among northern peoples until the latter part of the first millennium CE. By that time, reindeer husbandry had spread to the Nenets, Khants, Eveniks, and other Tungus-speaking peoples of northern Eurasia. However, the Sami (Laps) of northern Scandinavia evidently did not adopt the practice until recent centuries.

The invasion of the Roman, Chinese, and Persian empires by the pastoral peoples from the Inner Eurasian steppe in the fourth to the seventh centuries CE may have been an adaptation by the pastoral tribes to the increasingly dryer conditions on the steppe associated with the Dark Age Cold Period (200-650 CE). While frequent droughts led to social and political instability in the sedentary empires, they impelled the pastoral tribes to break through the imperial defenses. The spread of camel pastoralists from Somalia westward along the southern edge of the Sahara Desert may have resulted from increasing drought in the early part of the first millennium CE. The camel was better adapted to the harsh environment than were cattle. Later, the spread of camel pastoralism in the interior of the desert, together with the beginning

of regular trans-Saharan trade, by 700 CE may have been an adaptation to a moister climate.

It was in agriculture that the most diverse and widespread human adaptations to environmental constraints occurred. Population growth required more land under cultivation, and this in turn necessitated more extensive use of irrigation. In the richest agricultural areas of the world irrigation systems were extended and, where they had fallen into disrepair, refurbished. In the more arid regions, such as the Arabian and Sahara deserts, wells were dug, while in areas of seasonal rains, such as the Indian subcontinent, reservoirs and tanks were constructed. In mountainous areas such as in the Ifugao region of the Philippines and the Peruvian Andes, farmers built elaborate terraces for irrigation and to minimize soil erosion. In some territories, farmers protected their crops from cold and drought by ingenious systems. Farmers in parts of Polynesia and China created microclimates by planting taro and other crops in pits dug in the ground, and in North China peasants also protected crops against frost by planting them between earthen furrows.

One of the most sophisticated and effective farming systems employing man-made microclimates was that developed by the people of Tiwanaku in the first millennium CE. In this system, the farmers built raised fields in the wetlands near Lake Titicaca. The relatively small fields, separated by canals, were thickly planted with potatoes and other crops. Although the temperature of the air in the surrounding area at night often dipped below freezing, the warm water in the canals warmed the raised fields so that the crops escaped frost damage.

In these ways and others, societies in the early medieval age adapted to changing environmental constraints with some success.

Environment, Population, and Trade in Early Java

Early Java's economy and settlement patterns were consequent to geographical distinctions between coasts and hinterlands and uplands and lowlands. These divisions would result in regions of *sawah* (wet-rice) and *swidden* (garden, slash-and-burn, or shifting) cultivation. The trading exchanges involved both dichotomies. The earliest trade networked highland hunters and gatherers who exchanged their services and forest products (woods, bamboo, lacquer) with lowland rice cultivators. Salt from the coast was a key commodity in this upland-lowland exchange, although in this case the highland products stayed with the lowland cultivators rather than flowing on to the coast. Another type of exchange network was that between hinterland populations and coastal peoples and then outward to the international trade. In this second indigenous trading network, the hinterland supplied local agricultural and forest products to lowlanders who dispensed them externally to international traders. Coastal-based traders returned goods of foreign origin or specialized services (for example, transport) to the hinterland producers. In exceptional cases merchants worked from a coastal base to organize the necessary trade mechanisms that allowed them to extract local products from their hinterlands. However, this was rare. Agricultural and imported commodities normally entered Java trading networks either laterally, through direct barter between producers and consumers, or vertically, through political or religious institutions or through the developing hierarchical commercial networks. Barter was the primary means of exchange in earliest times, and only rarely was trade conducted by means of monetized commercial transactions until minted Chinese copper coinage became an alternative standard in marketplace exchanges during the fourteenth century.

Even in its early stages, sawah cultivation made a tremendous difference in social arrangements. Not only did it support a denser population, but the increased productivity of this relatively stable food source was an ideal means of feeding the non-food-producing individuals

associated with the state, including such people as political functionaries, religious specialists, and traders. Sawah cultivation and political development in early Java were thus coincident. The available inscriptions suggest that in the earliest period of Java's political development prior to the eleventh century, direct payment of tax revenues to a court was the exception rather than the norm, as it was more common for a political authority to reassign its income rights to the sustenance of local temples. Nevertheless, regardless of their initial use, the advent of surpluses controllable by a state was an important step in the development of Java's civilization.

In the earliest years of wet-rice agriculture, any attempts to tax the small and scattered productive units must have been a time-consuming task, if it was attempted at all. Nevertheless, as Javanese states developed, there would be an ongoing tension between the interests and abilities of producers and the politics that sought to draw on their surplus. On the one hand, despite the ready availability of productive land in adjacent lowland and highland forests, sawah cultivators could not easily and randomly escape revenue assessments. Leaving their fields uncontrolled was not an option for sawah cultivators except in the period immediately after the harvest, and efforts to develop new lands for cultivation (building terraced and irrigated fields) might require sustained work over several seasons. On the other hand, the armies and bureaucratic corps of the early states were not large enough to induce sawah producers to remit contributions of food or labor purely through the threat of force. Instead, would-be elites had to offer inducements such as protection or material or ideological rewards. In central Java even protection might not always be needed, as the population centers were geographically isolated from their neighbors and thereby minimized human threats to property, crops, and lives. While there was clearly competition among eighth- and ninth-century hinterland regional polities based in central Java's volcanic river plains, there was no hegemonic state. In that time, most commonly, political elites secured food and labor from subordinate sawah cultivators by means of material rewards such as foreign luxury goods or through ideological rewards such as titles,

temples, and sacred ritual rather than by threat of military intervention.

The late-tenth-century recentering of Javanese society and culture in east Java's Brantas River basin benefited from a direct connection to the ocean on Java's north coast. East Java-based monarchs sometimes intervened directly to build regional hydraulic irrigation networks in order to gain better control over agricultural production and increase its yields, not simply to control floods or regulate the water supply. One incentive for developing this control was the more significant financial position that long-distance trade had assumed in the East Java economy, particularly the rice-based trade to the eastern Indonesian archipelago via the Solo and Brantas rivers. However, the increased rice production encouraged by this trade was more the work of local producers than of the state, being produced voluntarily rather than extracted forcibly. A polity's authority certainly benefited from royal access to and partial control over the trade-derived luxuries. Furthermore, East Javanese courts took a more direct role in economic and administrative affairs than had their central Javanese predecessors. However, there is no evidence that even East Java's courts severely regulated local access to the imported commodities, nor is there evidence that they dominated the countryside and monopolized the rice trade by means of tax assessments, and even in East Java irrigation networks continued to be built and maintained mostly by the locals rather than the state. Thus, there was local incentive to invest in agrarian development to produce the surpluses that could bring trade luxuries to the local producers, and it was the locals who continued to control the irrigation networks.

A ruler would have had ample reasons to support the success of wet-rice cultivation. Above all, wet-rice cultivation could support relatively large population concentrations, and the population would in turn produce sufficient agricultural surplus to sustain the needs of a court. The concern of royal courts for their agrarian hinterlands would be an enduring theme of Javanese culture. A state's economic initiatives tended to focus on the development and preservation of sawah, both the creation of newly incorporated sawah communities and

the prevention of cultivated land's return to wilderness. Therefore, though sawah cultivation required more from the farmer, it also attracted support to the farmer from larger collectivities ranging from the village clusters all the way up to the monarch.

In addition to directly facilitating the construction and regulation of agricultural infrastructures, states would eventually concern themselves with providing security. To prevent reversion to the wild, a grassland periphery was commonly maintained. This area served as a border against the forest and a buffer against enemies. Here domesticated animals grazed, and here and in the adjacent forest both the court elite and the commoners hunted wild animals. By this time, the cultivators would have developed a very different attitude toward forests than they had as shifting agriculturalists. For swidden farmers, the forest is home. But for these sawah farmers, the forest was dangerous. So here too is evidence that the shift to wet-rice agriculture was part of a wide-ranging cultural shift whether or not it was actively encouraged by states, in further support of the notion that in at least some senses, this shift was a bottom-up development rather than one actively imposed by the states. Ultimately, sawah cultivators had a different attitude toward forests than that of swidden farmers. The controlled use of fire helped to maintain the border between the sawah and swidden zones of habitation while also replacing old taller grasses with shorter and younger varieties that provided better nutrition to livestock.

Hunts in adjacent forests provided sawah cultivators with necessary protein, culled animals that might damage crops, and helped to hone skills of balance, agility, and accuracy with weapons necessary for warfare. In Javanese court literature, royal hunts assumed importance as a ritualized display. Due to his control of the forest, symbolic of that which is wild and uncivilized, a monarch and his allied elite held the right to hunt royal game, which symbolized the victory of court civilization over prevailing localisms. In addition, the elite's rights to the products of forest hunts included such exotic export items as rhinoceros horn and tiger penis

(both considered to be aphrodisiacs), which figure prominently among Java's exports to China.

Environmental Constraints in Mesoamerica and the Andes

Civilizations in the pre-Columbian Americas faced two primary environmental constraints. First was the north-south direction of the Western Hemisphere that cut across latitudes and broke up weather systems with high western mountain ranges. The second was a lack of animals that could be domesticated for food, transport, and power. Together these two constraints took new world stone-age civilizations down a different historical path compared to old world counterparts, impacting populations, food supply, urban density, technology, and more.

Pre-Columbian populations for the entire hemisphere reached 50 million people by 1500 CE, or about the size of the Roman empire 2,000 years ago. The largest urban area of the Americas was Teotihuacan in central Mexico, with a population of perhaps 150,000 at its height. This was only a small fraction of the population found in classical empire capitals such as Rome, Patilaputra, or Chang'an in the old world. This light density resulted from adaptations to the environmental constraints of climate and lack of domesticated animals. The animals that played such a large role in old world civilizations were not present in the pre-Columbian world for use as major food, transport, or power sources. Animals such as horses, camels, cattle, oxen, water buffalo, goats, sheep, pigs, and chickens were

not present in the Americas, and instead indigenous peoples relied upon dogs, turkeys, llamas (camelids), and guinea pigs. Most transport and labor had to be completed by humans. For food, crops that could grow in a variety of environments such as maize, potatoes, beans, manioc, tomatoes, and gourds were supplemented with wild animals such as fish, crustaceans, deer, reptiles, rodents, and insects across the landscape using rudimentary technology. Not surprisingly, the pre-Columbian worldview including religious beliefs was devoted to managing this complex and precarious ecological relationship.

In Mesoamerica, irrigation crop technology produced yields beyond the carrying capacity of the land through *chiñampas* or intensive raised field agriculture. Swamp mud, water, and civilization debris were combined with vine plants such as tomatoes, beans, chilies, and gourds that grew around maize stalks watered by irrigation rows filled with fish, crustaceans, and other aquatic animals. The result was an incredibly productive plot that produced up to five crops in a year and was self-sustaining.

In the Andes as in Mesoamerica, extreme conditions of moisture and elevation combined to produce extensive agriculture variations. Terracing and irrigation allowed for various isolated environmental zones to be exploited. Quinoa grain was grown at elevations above 10,000 feet. Potatoes were produced in cold intermountain basins using irrigated water to moderate nightly temperatures, and cotton was produced on coasts with no measurable rainfall by gathering moisture from morning fog nets. As elsewhere in the Americas, crops were planted at several elevations and climates to ensure production.

Even this creativity, however, was not enough to overcome catastrophic environmental constraints in the Americas often associated with the north-south direction of the hemisphere, which meant exposure to global and regional weather patterns for latitudes between 0 and 60 degrees. Storm systems such as El Niños in the Pacific and hurricanes in the Atlantic as well as volcanic mountain chains on the Pacific Ring of Fire were coupled with earthquakes and rain-drought shadows that made for a turbulent history. Civilizations such as the Moche in South

ENVIRONMENTAL CONSTRAINTS AND TECHNOLOGY IN MESOAMERICA

In Mesoamerica the environment directed technological developments away from the use of the wheel and metallurgy. Both are found in the archaeological record but primarily as decorative. So why not as tools?

The environment was probably a major factor. With volcanic mountain ranges that ran north to south and reached 17,000 feet in height, the region was split in half. Additionally, two rugged coastlines on the Pacific and the Caribbean made coastal watercraft travel more efficient than land travel. Most important, the lack of draft animals (only turkeys and dogs were available) to pull wheeled vehicles and metal-edged plows favored stone-age transport and tools. Mesoamericans found it easier to travel by water, till fields with stone and wood hoes, and move goods by backpacks versus using soft, expensive metallurgical tools or to haul wheeled carts in the mountains, jungles, and deserts of Mesoamerica.

—Christopher Howell

America fell victim to El Niño flood events in the sixth century CE, while the Maya of Mesoamerica suffered repeated cycles of drought and ecological imbalance over 2,000 years of history. Even lightly populated southwestern Pueblos on the edge of Mesoamerica suffered from cyclical droughts that altered historical trajectories. Starvation and drought were always just an environmental change away. These events placed great stress on humans, plant resources, and wild game by disrupting an already stretched food and water supply. Archaeologists have noted associations between catastrophic events and human sacrifices in the pre-Columbian world, even to the point of cannibalism.

Even areas of civilization such as metallurgy and seafaring were impacted, though researchers are still unclear on the nature of such relationships. Some copper metallurgy was known, spreading late from South America to the north, but iron was apparently not utilized. Sails were known, and some unique watercraft were utilized in open ocean voyages, but as with metallurgy

little technological advancement was made, perhaps associated with environmental constraints. Both the Amazon region and eastern North America also demonstrate similar developmental patterns.

Pacific Ocean Islands and Australia—Environment and Population

Australia and the islands of Oceania were peopled in two great waves of migration flowing out of Southeast Asia. Australia and Melanesia were first occupied by modern humans tens of thousands of years ago, while Micronesia and Polynesia, among the last places on earth to be peopled, were first occupied only thousands of years ago. By 300 CE more than 1 million people, adapting to a wide variety of environments in different ways, lived throughout Australia and Oceania.

Australia and Oceania are made up of several types of geologic formations. Australia, New Guinea, and New Zealand are continental landmasses with a diversity of plants and animals. Of the smaller landmasses, many, such as Hawaii and Fiji, are high islands formed by either explosive or flow volcanic eruptions and by coral buildup and are less biologically diverse than the continental landmasses. The low islands of the Pacific, including most of Micronesia, are coral atolls only a few feet above sea level. Low islands are less biologically diverse than either continental landmasses or high islands.

Almost every type of climate zone known on the planet can be found in the Australia-Oceania region. In Hawaii alone, 11 of the 13 climate zones can be found. Environments throughout the region include seacoasts with saltwater-tolerant plants such as coconut palms, mangrove forests with plants adapted to brackish water, swamps with plants such as sago palms, lowland rainforests with a wide variety of palms, montane rainforests with oaks and pines, cloud forests with rhododendrons and myrtles, alpine forests and meadows, semideserts, grasslands, savanna woodlands, semitropical coniferous forests, and semitropical deciduous forests.

In Australia small bands of foragers achieved a sustainable adaptation that lasted tens of thousands of years. With a population of about 750,000, well below the carrying capacity of the land, Aboriginal peoples could withstand any shifts in the climate. Through periodic controlled burning of the land, native Australians both maximized those ecological niches that provided desired food resources and prevented large fires by minimizing underbrush as a fuel source for fires. While outsiders could point to the simplicity of an Aboriginal technology that lacked even the bow and arrow, the material culture of native Australians enabled them to live in harmony with their environment. No cultivation of domesticated plants ever developed in Australia, and the only semidomesticated animal was the dingo (dog). According to environmental scientist Timothy Flannery, the frequent extreme climate pattern of the El Niño–Southern Oscillation (ENSO) resulted in long periods of drought that made gardening unsustainable in Australia. Staple foods ranged from grass seeds and other bush tucker in the semideserts of the interior to palm nuts in the rainforests of the north.

Around 700 CE sweet potatoes were introduced into Oceania and spread west into Polynesia, Micronesia, and Melanesia. A plant first domesticated in South America, sweet potatoes were probably brought into the Pacific by seafaring Polynesians who made contact with the Native Americans of western South America. Sweet potatoes quickly became a staple food throughout Oceania and resulted in a major population increase in the highlands of New Guinea. Such contact with South America may have occurred

► FIRE-STICK FARMING AND ENVIRONMENTAL MANAGEMENT IN AUSTRALIA

Fire-stick farming, a phrase invented by archaeologist Rhys Jones, refers to the pattern of periodic controlled burnings of the land done over thousands of years by native Australians in order to manage the environment and maximize food resources. Australian Aborigines are usually thought of as foragers who never developed farming. Around the world and throughout history, foragers are thought of as having almost no impact on the environment. Humans were first thought to have had an impact with the Neolithic and the invention of farming. Fire-stick farming is a dramatic example of the impact that foragers can have on their environment. With the burnings of the land, underbrush, which could fuel a large dangerous fire, was kept to a minimum, and ecological niches that favored certain foods could be expanded. Controlled burnings are called farming because of the degree to which the environment is modified and because of the level of knowledge required to do burnings safely.

—Charlotte Neely

Grass fire in Kakadu National Park, Northern Territory Australia. Grass fires are a critical part of the normal ecology of the Kakadu flood plain; many plants in this region have seeds that will not germinate until they have been through a fire. For many millennia, Australian Aborigines have set fires to encourage the growth of edible tubers and other fire resistant foods, as well as to create pastures for grass-eating kangaroos. (Craig Ruaux)

during a major ENSO event that meant an extended period of winter westerly winds. A similar shift in the winds probably facilitated the earlier settlement of eastern Polynesia.

In Melanesia, including New Guinea, foraging for wild plants, animals, and fish became less important over the years. People made use of a wide variety of domesticated plants and animals, and the population eventually increased to the maximum number the environment could support. The nature of horticulture required vast amounts of land to lie fallow at any point in time. The most important food crops grown through gardening were sweet potatoes, yams, taro, and bananas. Domesticated animals included pigs, chickens, and dogs. Soon after the introduction of the sweet potato by 1600 CE (if not centuries before; there is disagreement on this) the carrying capacity of the land was reached and exceeded in New Guinea. A pattern

of revenge warfare developed in the highlands among tribes as a kind of population-control mechanism, while malaria served the same function in the lowlands. Between 1000 and 1600 CE the population of Melanesia is estimated to have grown from about 564,000 to 753,000, with the greatest population density in the highlands of New Guinea.

In Micronesia most land was near the shore, and often salt water percolated up through the ground even in areas farthest from shore. Therefore Micronesians were more dependent than others in the Australia-Oceania region both on saltwater-tolerant plants such as coconut palms and on fishing as sources of food. The period of global warming that began about 800 CE probably increased such dependence with rises in sea levels. Due to the importance of fishing, boat building was probably most sophisticated in Micronesia. The only source of fresh water was

from rain. In Micronesia as in Polynesia and much of Melanesia, a societal form called chiefdoms developed. With more rank and status, chiefs could get others to cooperate with food redistribution systems to ensure that no one went hungry. By 1000 CE the population of Micronesia was probably about 86,000.

In Polynesia especially on the high islands a variety of domesticated crops were cultivated, all brought by the first settlers. Those plants included taro, yams, sweet potatoes, bananas, breadfruit, and many others. Animals included pigs, chickens, dogs, and, unintentionally, the Polynesian rat. To maximize food production in Hawaii, irrigation systems and shoreline fishponds were developed. Throughout Polynesia chiefs assigned land to commoners, ran redistribution systems, and controlled complex societies that also included priests, navigators, and artisans. By 1000 CE the population of Polynesia was about 78,000.

During the period from 300 CE to 1000 CE there was much migration within Oceania. It was probably after 800CE that the first humans arrived in New Zealand, making it the last place on earth to be settled.

Environment and Cities in the Americas

During the classical era in Mesoamerica, a number of cities were created as ritual and governmental centers. Some of the cities achieved considerable size and power. By the end of the classical era, however, nearly all of these cities

had declined in population and vitality. Although archaeologists disagree about causes, most believe that a major cause was the degradation of the environment and ecological setting around the cities.

Teotihuacan, whose population at its height was probably 100,000 to 300,000, was the largest city in the Americas. Other cities were considerably smaller, but many important ones had populations of around 8,000. The smaller cities were mainly administrative and religious centers. The ruling elites and their retainers lived in them along with religious leaders, priests, and some traders and artisans. They were all dependent upon labor and food supplied by common peasants, who made up the majority of the population. These peasants lived in small villages and settlements outside the city proper but within close walking distances. They supplied the labor that created monumental structures, such as pyramids and palaces. More importantly, they also supplied the food and other necessities of life for the elites.

Mesoamericans lacked pack animals and wheeled vehicles. For the transportation of food and other goods they depended on porters, who carried loads on their backs. Rarely, some goods could be transported by canoe but only when rivers were available. Although a thriving trade existed between the different cities in Mesoamerica, it consisted mostly of exotic and easily transported goods such as cacao beans, colorful feathers, and obsidian. Food products, such as maize, beans, and squash, were too bulky to make their transportation worthwhile. Porters could carry a useful load only a small distance.

This lack of easy bulk transportation meant that food required by the cities had to be produced nearby. Most of Mesoamerica was a tropical rain forest with relatively poor soil. The normal method of farming this land was slash and burn, or swidden, agriculture. The vegetation on a plot of land was cut during the dry season and allowed to dry out so that it could be burned. The ashes that were produced enriched the soil. The plot was planted at the beginning of the rainy season, and a good yield could be expected. Within a few years, the productivity of a plot of land would decline thanks to weeds, insects, and exhaustion of the minerals in the

soil. Before a plot declined to the point where the yields were unacceptable, farmers would select another area and begin the process again.

Swidden agriculture required a large amount of land to support each person. Most of the land was not in production at any one time. Unfortunately, as a city's population grew, more food was required, and thus more land was needed. At some point, the land was unable to produce enough food to support the population.

Efforts were made by the Mesoamericans to increase the productivity of the land. The remains of massive irrigation and terracing projects have been discovered by archaeologists. The labor for these projects was supplied by the peasants under the direction of the elites. Although successful to a degree, the projects apparently helped create divisions between the peasants and the elites. As tensions over shortages of food increased, the peasants became more likely to either revolt against their rulers or to move to locations where they had smaller burdens.

Evidence also indicates that the very success of growing cities helped to undermine their future. Monumental structures required more resources, such as lime. To create the lime, cities such as Teotihuacan burned nearby trees. One result of the deforestation was the massive erosion of farmlands, resulting in smaller harvests.

Anthropogenic Environmental Change

"Anthropogenic" is a term used to refer to anything that has its origin in human activities. One of the most dramatic examples is anthropogenic environmental change, which has a long history.

Human actions have effected changes in the environment at least since people discovered how to make fire hundreds of thousands of years ago. Fires set by humans are said to have caused massive deforestation and desertification in Australia. According to many scholars, excessive predation by humans resulted in the extinction of the megafauna (large animals) in Australia, the Americas, and Siberia prior to 10,000 years ago. Some climate historians speculate that the global warming caused by the development of agriculture in the last 10,000 years prevented the onset of another ice age.

In 300 CE, the earth's environment differed from what it became 700 years later. Dense hardwood forests covered much of northern Europe, southern China, and much of central and southern Mexico. Elephants and rhinoceroses roamed southern China, lions still existed in western Asia, and in Madagascar there were pygmy hippopotamuses, large crocodiles, huge flightless birds, and many species of giant lemurs as well as giant tortoises. In Hawaii and other islands of eastern Polynesia, there were many endemic species of birds, including large flightless geese. Rapa Nui (Easter Island) was covered by a species of palm unique to the island that formed verdant forests.

In the Mediterranean region, northern China, and northern India, where cities had made heavy environmental demands for many centuries, environmental change was already evident. Excessive timber cutting had denuded much of the terrain in northern China and the Mediterranean region. In particular, the pasturing of goats and sheep in the Mediterranean region on the deforested hillsides prevented natural reforestation and turned these hill slopes into scrubland. In both northern China and the Mediterranean region, the massive deforestation had resulted in increased devastation by flooding. Through this process great malarial swamps were created along the coasts in Italy.

The imperial authorities in both northern China and the Mediterranean region were voracious consumers of forests. Timbers were lavishly used for the construction of the great monumental structures, such as the Coliseum, the aqueducts, roads, fortifications, and waterways. prodigious quantities of wood were burned to

make charcoal needed in the production of cement and plaster as well as for the large amounts of iron produced in China and India. In the Roman empire, much timber was used in fortifying the northern frontier.

In previous centuries elephants, lions, and giraffes had inhabited North Africa, but by 300 CE hunters had exterminated these animals north of the Sahara.

After the decline of the Roman empire in the fifth century CE, deforestation in the northern part of the empire nearly ceased. As the population declined, the pressure on the environment was no longer as severe. Many rural areas where land had been cleared for tillage reverted to wasteland and then to scrub forest. In the ninth century CE, the climate began to moderate as the Medieval Warm Period set in. The population in northern and eastern Europe began to increase, and new lands, which were by then heavily forested, were cleared for farming. Deforestation resumed as new towns were built and cities sprang up in what had been previously the northern forest. The forests on the north coast of the Mediterranean began to be cut to furnish timbers for the ships needed in the revived commerce of the Mediterranean and for the navies of Muslim and Christian states. Many mountain slopes in what is now Slovenia were denuded of trees to furnish timbers needed as piles to drive into the Venetian lagoon on which to build the structures of the rising port city and naval power.

In northern China also, many Han Chinese fled south to the Yangtze Valley and beyond, abandoning their land to the conquering nomads moving in from the steppe. Rather than revert to forest, some settled lands were used to pasture the horses of the conquering nomads. In the south, the relocating Han Chinese commenced to displace the southern indigenes on the most productive and easily farmed land. The new Han settlers resumed the process of deforestation that had denuded northern China, and they began to hunt out the elephants, rhinoceroses, and tigers. These would be extinct in much of southern China by 1000 CE.

By 300 CE, Madagascar had been settled by humans for perhaps two centuries, but it still had most of its unique flora and fauna as well as

most of its widespread rain forests. There were giant grazing lemurs as well as giant flightless birds related to the ostrich and extinct New Zealand moa, dwarf hippopotamuses, great river crocodiles, and many other species, which the Austronesian settlers would drive into extinction by overhunting or habitat destruction in the coming centuries. The settlers, who were, with Bantu arrivals from Africa, the ancestors of the Malagasy, cleared much of the rain forest to grow the rice that they had brought from their Indonesian homeland.

In Hawaii and many of the other islands of eastern Polynesia, the settlers established their Polynesian crops and livestock (pigs, chickens, and dogs) but exterminated many of the endemic species of birds and some of the native plants. The pigs and the Polynesian rat, that unwelcome passenger on Polynesian voyages, did especial environmental damage by eating the eggs and young of ground-nesting birds. The early Hawaiian settlers hunted to extinction the large flightless Hawaiian goose. On Rapa Nui (Easter Island) the Polynesian settlers began their prodigal clearing of the Easter Island palm forest. In future centuries this would result in the extinction of the Easter Island palm tree and the relegation of the inhabitants to starvation and desperation.

In the Americas, the most devastating examples of anthropogenic environmental change were in Mesoamerica: the collapse of Teotihuacan and the fall and desertion of the classic Mayan cities. Teotihuacan was the largest city in the Americas and among the largest in the world from the third century to the seventh century CE, with a population that some estimate approached 300,000. It was a gigantic task to supply this metropolis with food, raw materials, and timber, since Teotihuacan was inland and not on a navigable river. The Mesoamericans had no draft or pack animals to pull or carry supplies to the city and, in the absence of river or sea transportation, the principal carriers of supplies to the city were humans. It was possible to supply the city's large population when the crops in the vicinity of the metropolis were abundant and the supply of timber was nearby. Over the years the nearby forests were cut, requiring carriers to make much longer journeys for timber supplies;

in the sixth century, droughts and crop failures compounded the difficulty of supply. Food shortages and starvation resulted in social and political unrest, which may have been exacerbated by foreign invasions. By sometime in the seventh century, the city collapsed and was soon deserted.

The collapse of the classic Maya cities is similar. At its zenith in the ninth century, the combined population of the classic Maya cities has been estimated at about 12 million. The forests had been cut not only to make room for farmland but also to provide timbers for the massive construction projects of the Mayan kings. When the great droughts of the tenth century set in, the land became a veritable dust bowl, and recurrent widespread famines reduced the population to a fraction of what it had been in its heyday.

These are the most noticeable examples of environmental change caused by human actions. Anthropogenic environmental change was and continues to be constant and incremental. This change accelerates as populations grow and becomes more serious as the technological capacity of humans to effect change becomes greater.

■ Introduction: Demographic Change

All population estimates for this era are, at best, guesses, based on a paucity of evidence. Our estimates start with an actual census taken in China during the mid-Han dynasty, at about the beginning of the Common Era. This census was an enumeration of the number of households. Historical demographers using this data have calculated China's population during the most prosperous years of the Han dynasty at about 60 million people. On the assumption that China's population remained stable or grew very slowly until the "barbarian" invasions in the fourth century, it is estimated that China's population in 300 CE was still about 60 million.

China's agriculture for at least the last 2,000 years has been the most intensive and productive in the world. In the nineteenth and early twentieth centuries, Chinese agriculture supported a fifth to a quarter of the world's people, and scholars have assumed that this has been the case for the last two millennia. If in 300 CE China's population of 60 million was one-fourth (or perhaps a

little less) of the world's population, then the total number of the earth's inhabitants was in the range of 200 million to 240 million.

Other historians, examining data from the Roman empire, estimate that its population in 300 CE was also about 60 million. The other region with high agricultural production capable of supporting a comparable population was the Indian subcontinent. Estimates for the subcontinent are not as high as those for China and the Roman empire, averaging about 45 million. But if to this figure is added the possible 15 million from Iran, Mesopotamia, and central Asia, we get 180 million.

This leaves Southeast Asia (2 million?), Japan and Korea (2 million?), Siberia and northern Europe (3 million?), and the Arabian Peninsula (3 million?) as well as sub-Saharan Africa, the Americas, Oceania, and Australia to be accounted for in terms of population.

To estimate the population of the Americas, scholars begin with archaeological evidence that points to a population of the Maya cities at 10

million to 12 million in the eighth century. In 300 CE, the Maya population may have been a third of that, 3 to 4 million. The population of the rest of Mesoamerica may have exceeded that, bringing the total population of Mesoamerica up to 6 million or 7 million. The other major population region of the Americas was that of the Andes, with possibly 3 million people. The rest of the population of the Americas in 300 CE might have been 3 million to 5 million, putting the total for the Americas in 300 CE in the range of 9 million to 15 million people.

Sub-Saharan Africa's population before the diffusion of bananas and other Asian crops was very small, probably not greater than that of the Americas, perhaps 15 million. Oceania and Australia together may have had 1 million or perhaps 2 million (depending on what the population of New Guinea might have been).

This gives us a grand total of earth's population in 300 CE of 220 million (200 million–240 million). Seven hundred years later, in 1000 CE, the Chinese population is estimated to have been 80 million. Using our assumption that the Chinese population was one-fourth to one-fifth of the world's total, the total world population would have been 360 million to 400 million people. That is not an impressive increase for three-quarters of a millennium, but it masks some serious population crashes as well as a few population blooms. These demographic changes roughly parallel climate change, the changes in temperature and rainfall over long periods, as well as perhaps changes in the disease environment. We know of one serious pandemic (Justinian's Plague) that swept Eurasia in the sixth century, but there are hints of other serious epidemics that affected wide regions.

In general, populations in mid-latitude Eurasia seriously declined during the Dark Age Cold Period (200–650 CE), but during these centuries populations grew swiftly in Mesoamerica, the Andes, and probably the Amazon and Mississippi basins. Conversely, during the centuries after 800 CE, populations in Mesoamerica and the Andes crashed, while those in temperate Eurasia responded to the more salubrious climate of the Medieval Warm Period by growing steadily and comparatively rapidly.

—Wilfred J. Bisson

Population Fluctuation and Ethnic Changes in Early Medieval China

The end of the classical era of Qin-Han (221 BCE–220 CE) in China was followed by a long period in which the population fluctuated greatly due to political instability, a contracting economy, and an increasing level of violence in society. At its zenith around the first century BCE, the population of China stood at 59 million, according to the government's statistics. Small landholding peasants constituted the bulk of the tax-paying and labor-supply segment of the population, through which the Han dynasty built its power and influence throughout the realm. Toward the second century CE, however, magnates at the regional level, based on large landowning families, gradually expanded their influence at the expense of the local peasants and thus eroded the foundation of the dynastic rule.

As central Han control weakened and the peasants increasingly suffered under growing regional power, social violence was on the rise. By the early fourth century CE, imperial authority was no longer able to restrain the power of the large estates, and the empire fell apart, giving way to the intensive competition among the regional power centers and indirectly putting tens of thousands of refugees on the roads. Productive agricultural land was left untilled, towns and villages were abandoned, and corpses littered the roadsides. Population declined rapidly; only a fraction of it remained on the government's tax roster.

The radical fluctuation of population was accompanied by drastic movements of ethnic groups within and from outside China. Increasing social instability prompted foreign invasions from the other side of the Great Wall. The fall of the Western Jin in 317 was followed by a period known as *wubu luanbua*, or “Five Barbarians, bringing turmoil to China.” These nomadic invaders spoke languages other than Chinese, and their invasions devastated the Chinese Central Plain, the heartland of Han society. The ruling Jin dynasty fled south to the Yangtze River valley. This huge influx of government officials, bureaucrats, and soldiers who accompanied it infringed on the local population, most of them

speakers of Austronesian languages. As a result, the ethnic makeup in the Yangtze River valley and farther south changed drastically.

In the Yellow River valley to the north, there were also changes in the ethnic makeup of the region. Upon their arrival at the fertile agricultural lands there, many of the invading nomads settled, and they founded, separately, 16 kingdoms in the Central Plain, many of them of short duration. In the early fifth century, one group of invaders, the Tuoba tribe of the nomadic Xianbei people, established a fairly stable state. Their dynasty, the Wei, carried out a policy of encouraging their people to *hanhua*, encouraging their people to adopt the Chinese language as well as the farming and government system of the Central Plain. Inter-marriage between the Tuoba and the native peoples of the Central Plain was common.

Ethnic mixing in this period continued for several centuries as locals intermarried with settling invaders. The Yang family, the founding dynasty of the Sui in 587, and the Li family that founded the Tang to replace the Sui in 618 both had a long tradition of marriage with non-Chinese-speaking peoples. By the mid-eighth century, the Chinese population grew to its highest level given the stability under Tang rule. By then, the ethnic makeup of China had changed considerably.

Fluctuating Populations in Inner Eurasia and Europe

The population of Europe and of Inner Eurasia (most of Russia, Belarus, Ukraine, and central Asia as well as Inner and Outer Mongolia and the

THE MYTH AND REALITY OF *HANHUA*

Different non-Chinese-speaking peoples who lived in the periphery of China often moved to rural areas of the country in their quest for economic expansion or territorial gain. After living in China, many of these recent arrivals adopted the Chinese lifestyle, language, customs, social and cultural norms, and political institutions. The Chinese had long noted this phenomenon and referred to it as *hanhua*, or *Han-ization*, with *Han* meaning “authentic Chinese culture.” However, these non-Chinese-speaking peoples also brought to China their own traditions and were instrumental to the syncretic nature of the development of subsequent Chinese culture.

—Yi Li

Chinese provinces of Sinkiang and Gansu) fluctuated dramatically during the first millennium CE as empires rose and fell. Droughts, famines, diseases, wars, natural disasters, and other calamities all took their toll. Following these events, the establishment of stable governments combined with the decline in mortality, a rise in birth rates, and the beginning of the Medieval Warm Period generated an increase in the population of these regions.

The stability created throughout Europe by the formation of the Roman empire under Augustus Caesar in 27 BCE and Rome's general policy through the Antonine emperors during 97–180 CE of fostering the union between the west and the Greek-speaking east allowed for substantial population growth. Population in Europe west of Russia reached a high point around 200 CE when approximately 36 million to 44 million people were settled in the region, this in spite of the Antonine Plague (165–180) during which an estimated 5 million people died. During the same period, the population of Inner Eurasia is estimated to have been anywhere from 6 million to 17 million. (Figures for Inner Eurasia do not include the population of Gansu.)

Population fluctuations in the distant past are difficult to track, but we can estimate them from evidence provided by anthropologists, archaeologists, and paleontologists. Some of the data is physical, such as the presence or growth

THE MEDIEVAL DEPOPULATION OF ROME

The population of second-century Rome may have been 1.2 million. After Visigothic and Vandal invaders sacked the city and destroyed the water supply system in 410 and 454, the population declined precipitously; only a few hundred thousand remained in the mid-fifth century. Famine caused by the volcanic eruption of 535 as well as by the seemingly endless wars caused further massive reductions in the population. As the Roman infrastructure crumbled, trade became more difficult, and an increasing lack of hygiene led to more illnesses. By the end of the sixth century the Roman population had been reduced to as few as 30,000. What was once the center of the Roman entertainment and the scene of bloody gladiatorial fights became a sheep pasture.

—Linda Malcor

Rome's defenses are breached by the Vandals, nineteenth-century engraving. By the mid-fifth century, the Roman empire was in steep decline and had already ceded most of its African colonies to the combined forces of the Vandals. Wars and invasions accelerated the population decline in the Late Roman empire already begun by adverse climate change and pandemics. (Ridpath, John Clark. Ridpath's History of the World, 1901)

of settlements and signs of agricultural activity. Other data is provided by calculations based on what we know about population density and probable birth and mortality rates in cultures with certain levels of technology and certain types of social organization. Population figures provided in ancient written sources are often large figures that simply mean “a lot of people,” so all such references must be checked against the other data that is available. Even so, population estimates found in different sources can vary widely. The numbers presented here represent estimates, and even these estimates cover a significant range.

As the stability of the Roman empire began to crumble under the Severans (196–217 CE) and

the subsequent emperors in the third century, the peoples of Europe were exposed to many threats that took a disastrous toll on their numbers. The warfare caused by the Eurasian peoples flooding into Europe reduced the population in that region to about 30 million. By 600 CE the European population fell to roughly half of its 200 CE level, somewhere around 20 million to 26 million, with about 25 million people dying during the Justinian Plague (541–542) alone. As stable states re-formed during the medieval period, Europe's population rose again, reaching around 30 million to 36 million by 1000 CE.

The population of Inner Eurasia may have remained a bit steadier largely because of its sparser population, which hindered the spread

of the pandemics that wreaked such havoc on Europe's population. The fall of China's Han dynasty in 220 destabilized much of the region, resulting in a decline in population that was reversed only by the establishment of the Sui dynasty in 581. Sources disagree about whether the population of Inner Eurasia fell by half a million or rose by a million between 200 and 400, but given the number of people leaving Eurasia and those killed in natural disasters and warfare, the figures indicating a decline make more sense. By 600 Inner Eurasia's population had either dropped by a little over half a million or risen by almost the same amount, with estimates varying from 7.4 million to 15.9 million people. The variations arise partially from the mass movements into Europe by nomadic cultures, such as the Alano-Sarmatians and the Huns, and partially because of natural disasters, such as the 535 volcanic eruption, probably of Krakatau, which caused an extreme climate change that resulted in famine and disease throughout Eurasia. By 1000, however, the population of Inner Eurasia, encouraged by the stability imposed by the Sui and Tang dynasties, definitely exceeded its 200 level, reaching between 9.6 million and 19.5 million people.

The natural disasters of the first millennium were followed by the Medieval Warm Period (ninth through thirteenth centuries), a time of elevated temperatures that occurred from roughly the tenth to the fourteenth centuries. Agricultural production increased during the Medieval Warm Period, and the population of Europe more than doubled again, to between 74 million and 79 million people, prior to the onset of the Black Plague. Although not impacted by the warmer temperatures, the population of Inner Eurasia increased to roughly 12.25 million to 19.3 million people during this time as nomadic cultures began to give way to increasingly agricultural societies and governments stabilized, encouraging population growth.

Justinian Plague

The Plague of Justinian was a series of outbreaks of what was probably bubonic plague—a bacterial infection spread by rat-borne fleas—in the Mediterranean basin and probably western Europe. These outbreaks lasted from 541 (during the reign of Byzantine emperor Justinian) to around 760. The first outbreak was the deadliest, killing millions of people and further weakening the eastern Roman and Sassanid empires, which were locked in perennial warfare in the Middle East. The outbreaks continued at various

Detail of a Byzantine mosaic of Emperor Justinian I from the Hagia Sophia, Istanbul, Turkey. During Justinian's reign (527–565 CE), the Byzantine empire won notable victories in recovering Italy and North Africa, but these victories proved hollow, largely because of the losses in population occasioned by the Justinian Plague. (Christel Gerstenberg/Corbis)

➤ PROCOPIUS ON THE PLAGUE

Procopius, a sixth-century Byzantine historian, made these observations about the plague's symptoms:

"I am unable to say whether the cause of this diversity of symptoms was to be found in the difference in bodies, or in the fact that it followed the wish of Him who brought the disease into the world. For there ensued with some a deep coma, with others a violent delirium, and in either case they suffered the characteristic symptoms of the disease. For those who were under the spell of the coma forgot all those who were familiar to them and seemed to lie sleeping constantly. And if anyone cared for them, they would eat without waking, but some also were neglected, and these would die directly through lack of sustenance. But those who were seized with delirium suffered from insomnia and were victims of a distorted imagination; for they suspected that men were coming upon them to destroy them, and they would become excited and rush off in flight, crying out at the top of their voices. And those who were attending them were in a state of constant exhaustion and had a most difficult time of it throughout. For this reason everybody pitied them no less than the sufferers."

intervals, preventing the Mediterranean populations from recovering fully and leaving them vulnerable to invasion. In the end, the disease simply disappeared from the West for no known reason.

Contemporary sources claim that the first epidemic began in Egypt or farther south in Africa and spread by ship across North Africa and the Levant to Constantinople, Italy, and southern France. It may have also appeared in England and northern Europe west of the great German forests during the seventh century. No one in the early medieval world was prepared or equipped to deal with disease on any level, especially one

that spread as widely and killed as readily as this plague.

Most secular or medical writers followed the teachings of the classical physicians Hippocrates and Galen, blaming the epidemic on corrupted air, perhaps caused by comets, fires, or earthquakes. Most religious writers credited the plague to God, usually seeing it as a punishment for human sin, not unlike the great flood in Noah's day. Many writers listed the typical symptoms. Late in the sixth century Evagrius, a lawyer in Antioch, lists buboes, fever, diarrhea, carbuncles, and swollen and bloody eyes. Gregory, bishop of Tours in France in the century's last decades, described what he saw: "Death was very sudden. A snake-like wound appeared in the groin or armpit and the poison affected the patients in such a way that they gave up the ghost on the second or third day. Furthermore, the power of the poison robbed people of their senses."

Swellings in the lymph nodes of the groin, armpit, or neck are common signs of bubonic plague. In northwestern Italy historian Paul the Deacon wrote in the late 700s that "there began to appear in the groins of men and in other delicate places, a swelling of the glands, after the manner of a nut or date, presently followed by an unbearable fever, so that upon the third day, the man died. But if anyone should pass over the third day, he had a hope of living."

The fear of death caused Byzantines to wear name tags when they went out so they might be identifiable if they should die in the streets or while traveling. They used scents and aromatic smoke to cleanse the corrupted air they thought caused the disease.

Administrators and bishops ordered mass graves dug to accommodate the huge numbers of the dead, and contemporary estimates of fatalities run wild. Yet even modern estimates for deaths in Constantinople in 541–542 range around 40 percent, or 200,000, out of a base of 500,000. All told, as many as 25 million, perhaps a quarter of all Mediterranean people, died over a three-year period.

By the end of the pandemic the ancient world had been transformed. The role of the plague in this transformation is debatable but undeniable. Bulgarians and Slavic peoples had migrated into and secured the plague-wracked

Balkan region, Justinian's reconquests from the Goths in Italy quickly fell to the Germanic Lombards, and the Muslim Arabs burst out of the Arabian Peninsula to create an Islamic empire that stretched from Spain to Baghdad, much of it on the ruins of the Sassanid and Byzantine empires. Large death tolls among their enemies may have also facilitated the rise of the Frankish kingdom in Gaul. Cities such as Constantinople, Alexandria, and Damascus suffered terribly, losing perhaps half of their populations. The numerous deaths of craftspeople, artists, teachers, and other specialists precipitated the decline of many cultural characteristics, from rising illiteracy to less classical forms of artistic expression.

Society and Culture

During this age, the great majority, perhaps as many as 90 percent, of the earth's people were members of sedentary agricultural societies. Most of these sedentary agricultural societies were organized into states and empires, but some were stateless, organized as chieftainships or autonomous villages. The next largest group of the earth's inhabitants (after sedentary agriculturalists) were nomadic or seminomadic pastoralists who herded cattle, yaks, horses, sheep, goats, camels, lamas, or reindeer. These groups formed widely diverse social structures that varied according to environmental factors, the nature of neighboring sedentary agriculturalists, and other historical factors. A very small fraction of the world's population during this period was nomadic or seminomadic hunters and gatherers, some of whom were also gardeners.

A few groups of hunters and gatherers whom lived in particularly rich environments, such as Florida, California, or the North American Northwest, lived in sedentary but nonagricultural villages and comprised a separate group of cultures.

Our knowledge of the society and cultures of hunting and gathering people in the Age of Expanding Regional Civilizations is anecdotal at best and suffers from extreme paucity of sources. We know more about societies and cultures of the pastoralists than of hunters and gatherers of this age, but what we know is still largely anecdotal and is biased toward the views of their sedentary neighbors. Consequently, this essay mostly concerns itself with the societies and cultures of the sedentary agricultural peoples who lived in states or empires. But that included the great majority of the world's inhabitants.

During this age, as in all periods of human history, the basic social institution was the family. Although human societies included a wide variety of family structures, the vast majority of families in sedentary agricultural populations during this period were patriarchal, patrilineal, and patrilocal. They were patriarchal in that the father was the head of the family, patrilineal because descent and inheritance followed the male line, and patrilocal because married couples usually lived with or near the husband's kin.

In China and in Christian lands, men were allowed to have one legal wife, while four were allowed in Islamic countries. But this does not mean that a form of polygamy was not allowed in Christian Europe or in China. In both areas during this period, concubinage and other forms of female slavery were allowed, recognized, and widespread among the elites of all major agricultural societies. For example, the Christian kings of the Franks, including Charlemagne, all had several concubines

in addition to their legal wives. The restriction of elite men to one wife was to control inheritance, not sex. Non-elite men were restricted to one wife, and poverty usually precluded them from keeping concubines.

Marriages were regarded as social and economic contracts between the families of the bride and groom and were always, with rare exceptions, arranged by the families concerned. Rigid rules of procedure were followed. Usually, the bride's family provided a dowry, which in

India could be a substantial part of the family's wealth. In China and India, the most elaborate procedures were followed, with matchmakers often licensed by the state.

Girls were married young, often before puberty. In Tang China the minimum age for marriage for a boy was 14, while girls were often married by the age of 12. In Muslim lands, girls as young as 9 were sometimes wed.

Girls were married young, often before puberty. In Tang China the minimum age for marriage for a boy was 14, while girls were often married by the age of 12. In Muslim lands, girls as young as 9 were sometimes wed.

Families varied with social classes. Upper-class households might be vast extended family agglomerations and include multiple nuclear families, dominated by a patriarch, whereas peasant families were often single nuclear families and usually included only three generations in the same household.

Women, who usually moved from their natal families to the families into which they married, became subservient to their mothers-in-law. In China as in India, new brides occupied the lowest status in the family hierarchy. It is sometimes said that in China, daughters-in-law paid the highest price for the social structure.

In the most complex and technologically advanced agricultural societies, such as China and India, the subjugation of women in the social order was most complete, whereas in the less complex and less technologically advanced areas, such as western Europe, male dominance was less pronounced. Among the nomads of the Eurasian steppe, gender roles were less rigidly defined, and strong women sometimes emerged.

Agricultural societies were, with rare exceptions, hierarchically stratified. They were divided into numerous social gradations, with a small elite ruling class and massive classes of farmworkers. In between these were intermediate groups, such as military men, merchants, artisans, monks and nuns, and urban people in general.

The farmworkers ranged from free peasants (who rented and sometimes owned the land they worked) to serfs and then to agricultural slaves. These farmworkers comprised 90 percent or more of the early medieval population. They lived in tens of thousands of often-isolated villages, each with its own cultural and linguistic dialect. Many of these villages had little contact with other villages. Each village was a world unto itself. Most of these isolated villages had their own traditions, historical narratives, and folk culture. The free and unfree peasants in these villages produced most of the societies' wealth and taxable revenue. They were the strength and support of all agrarian societies, yet they were disdained and discriminated against in all lands.

In most agrarian societies, a wide chasm separated the peasants and the ruling elite. The rulers lived in fortified capital cities and enjoyed the luxury and wealth drawn from all the villages in their domain. The size and opulence of the city reflected the number and prosperity of the villages under its rule. The high culture of the cities and elites affected the villagers in a limited way, as it was mediated through the agency of the culture brokers such as merchants, tax collectors, clergy, soldiers, and landlords.

In China and in some of the Islamic lands where money circulated freely, governments supported their military establishments through taxation, and the soldiers lived in cities of special camps, with only occasional interaction with the villagers. In less economically developed regions, such as western Europe or northern India after 600, rulers assigned military men a village or villages, with its land for their support. By this method, the military men acquired “ownership” of the villages and a claim on the produce and labor of the villagers. In western Europe this system led to feudalism, and in India as well as some Muslim countries it led to something similar to feudalism. In these systems, peasants were required to render payments in money and/or kind to their lords as well as to labor a number of days weekly or monthly for the lord. Where such systems prevailed, the military aristocracy built manor houses in the countryside and developed more intimate relations with the villagers.

Groups of religious specialists also constituted an elite that drew its support from the peasants. Most of these religious specialists were monks or nuns who lived in monasteries to which the rulers had granted peasant villages for their support. The monasteries were then the landlords of these villages and had a claim on their produce and labor. Monks and nuns, Christian, Buddhist, or Hindu, were relatively numerous in most agricultural societies in this era. In mid-ninth-century China, the Tang emperor Wuzong launched a great suppression of Buddhism and other religions regarded as foreign to China, in which reportedly 4,600 Buddhist monasteries were dissolved and their 260,500 monks and nuns defrocked and returned to lay life. The dissolution of these institutions returned 150,000 serfs to the tax rolls. In addition, 3,000 Manichaean, Assyrian Christian, and Zoroastrian clerics were expelled from China. But these monks and nuns did not comprise the total in China; in addition, there were over 1,000 Daoist monasteries and more than 100,000 Daoist monks and nuns who were not included in the persecution. After Wuzong died in 846 the persecution ceased, and many of the dissolved monasteries were revived.

In western Europe during this period, the number of monks and nuns in relation to the lay population probably equaled that of China except in Ireland, where the ratio may have been higher. In India, in addition to Buddhist monasteries, there were Jain monasteries as well as a variety of Hindu institutions.

Besides the religious specialists, the social status of the many groups between that of the ruling elite and the peasants varied. There were traders, who ranged from great merchants involved in oceanic shipping or long-distance caravan trade to the village peddlers. There were craftsmen

and artisans who produced a wide variety of goods from glassware and cloth to pottery and from iron tools and armor to steel blades. They ranged from those who worked in large establishments, such as the great ceramics establishments in China, to the small smithies in the forest clearings and castles of western Europe. There were medical practitioners, scribes and clerks, moneylenders and changers, and others. Special groups who passed the mysteries of their trades from father to son or mother to daughter practiced most of the arts and crafts.

In many lands, such as West Africa, Mesoamerica, Muslim cities throughout the vast and growing Dar al-Islam (Home of Islam), and India, practitioners of specialized trades banded together in guilds for protection and social expression. Increasingly, these guilds practiced endogamy (marriage only within the guild) and evolved into castes. In

Increasingly, these guilds practiced endogamy (marriage only within the guild) and evolved into castes. In India and perhaps also in West Africa, the evolution of guilds into castes had an ancient pedigree and was well advanced before this era.

India and perhaps also in West Africa, the evolution of guilds into castes had an ancient pedigree and was well advanced before this era.

In India, the caste system was most highly developed. Most people, except the lowest social status, belonged to castes (*jati*). Castes were (and are) social groups that have similarities to a very large extended family or a nation. They are endogamic (marrying only within the group)

hereditary social identification groups, sometimes with formal organizational structures, that often are associated with given occupations and economic functions. Although Indian society had been divided by castes for centuries and perhaps millennia, in this era the boundaries between castes grew more rigid as craft and mercantile guilds claimed exclusive occupational niches and evolved into new castes. The lot of the low caste (or outcaste) untouchables became more debased, and caste rules governing ritual purity became more rigid.

All agrarian societies, most societies of pastoral nomads, and some sedentary foraging societies kept slaves in late antiquity and the early medieval age. Indeed, slaves were considered indispensable for the proper functioning of a society. Slaves were used in many occupations and occupied a variety of social statuses. Most did menial labor and ranked very low in the social hierarchy, but a few, who were associated with the elites or served as soldiers, had higher social ranks. Many slaves worked in agriculture. As many as 20 percent of West European farm laborers may have been slaves in Carolingian times (eighth through ninth centuries). In the sugar-planting region of southern Iraq, the population consisted overwhelmingly of slaves from East Africa, many of whom revolted in a series of uprisings, the most serious being in 869–883. Some slaves were entertainers, and many were trafficked as prostitutes.

Some people fell into slavery when they could not pay their debts. In hard times, such as during the famines that recurrently swept through almost every region, people sold themselves and their children into slavery. But many slaves were prisoners of war or captives of slave-raiding expeditions. Vikings launched slave raids into Ireland, western Europe,

and Russia. Expeditions from the Muslim caliphates captured many Turkish slaves, while the Carolingian and other West European states kidnapped many East Europeans, making the ethnic designation “Slav” (*Sclavus*) synonymous with “slave.” In Tang China, there were legal and cultural obstacles toward enslaving ethnic Han Chinese, but it was legally very easy to enslave Koreans, the indigenes of southern China, or the so-called barbarians from the northern steppe. And in India, it was easier to enslave the tribal people than members of established castes.

Agrarian societies that were organized as states or empires, as well as some pastoral empires, had at minimum a capital city and often other cities. The chief economic role of the cities was the care and feeding of the soldiers and elites who supported the state or empire and benefited from its bounty. The ruling elite, the religious elite of clerics and monks/nuns, the imperial bureaucrats, soldiers, craftsmen and artisans, merchants, laborers, servants, entertainers, prostitutes, slaves, and others inhabited the cities. Some, especially the servants and many slaves, lived with the elite in their great houses, but most of the artisans and merchants as well as the humble laborers and others lived in their separate quarters of the cities. As the cities grew, artisans and merchants banded together in guilds, especially in Islamic and Indian cities and later in western Europe. As we have seen, Indian guilds often evolved into castes.

The high culture of these cities often differed widely from the popular cultures of the rural villages in which the majority of this era’s people lived. The culture of the town dwellers was often shaped by one of the world religions—Buddhism, Islam, Christianity, Saivite, Vaishnavite Hinduism, and, to a lesser extent, Judaism—that were vehicles for the expanding regional civilizations of this era. In the cities of this era, the piety of the dominant world religions was triumphant, while the rural villagers clung to the paganism of their folk religions. Throughout this era, the cities served as the bridgeheads for new ideologies: Buddhism in East Asia, Christianity in the Roman empire, and (after 632) Islam in West Asia and North Africa. The religion of the cities, as well as their high culture, flowed, usually slowly, from the cities to the rural villages.

In the dominant civilizations of the Afro-Eurasian ecumene, the Age of Expanding Regional Civilizations was an age of faith, and all societies subscribed to an official religious tradition. Religious institutions dominated the cities and were spreading into the countryside. Religious doctrine shaped the legal structures, social mores, and public monuments as well as literature and art. Christian churches had their own courts to police morals and matters such as marriage and divorce thought to be in their purview. In Muslim societies, legal issues were the provinces of specialists in Islamic jurisprudence, or *fiqh*. China was probably the most secular of these early medieval societies, but even there, the Confucian secularism of the Han dynasty was overshadowed by the Buddhist and Daoist religiosity of the Tang.

In all agrarian societies dominated by cities (that is, the great majority of societies), the educational system, centered in the cities, disseminated the high culture of that civilization. These educational systems were usually meant to train a very small percentage of the population as religious specialists and candidates for the bureaucracy. In China the

emphasis was on the latter, and the Chinese educational establishment included the most formal examination system devised by any early medieval people. In China, India, and Srivijaya, Buddhist monasteries functioned as teaching institutions as well as places of religious devotion. The Buddhist monastery of Nalanda, in India, had international renown and drew students from China, Japan, and Korea as well as Southeast Asia. Among Hindus in India, higher education usually involved being tutored by a guru, but late in this era, the great Hindu reformer Shankara established *mathas*, or monastic colleges, in imitation of the Buddhist monastic academies. In Muslim and Christian lands, education was less attended, and institutions for higher learning were slow in developing. In Constantinople, the government maintained a school, the Pandidakterion (“The Place Where All Things Are Taught”), sometimes called a university by modern historians, to train high functionaries in church and state, but that was the closest approach to higher education in Christian lands since the suppression of such institutions in the fifth century. In Muslim lands, the tradition of classical Greco-Roman learning was kept alive by Assyrian Christian teachers at the Persian school of Gondeshapur in Edessa (Syria), but the first Muslim madrassah of higher learning was al-Azhar in Cairo, founded by the Shia Fatimid dynasty in 974. In a number of cultures in Africa south of the Sahara, education was one of the functions of age-group cohorts.

In all early medieval societies, material culture complemented verbal and other nonmaterial aspects to produce the cultural imprint of the age. The production, preparation, and consumption of food as well as the clothing worn, the types and locations of the dwellings, the kinds of tools and utensils, the kinds of sculpture, paintings, and other plastic arts employed, and the religious and other public monuments all contributed to the cultural signatures of the age.

Each civilization had its own foodways, its distinct pattern of culinary experience. The Chinese and most other sedentary East Asians disdained dairy products, but milk and cheese were the principal dietary elements for the pastoral peoples. For the South Asians, the people of the Muslim world, and the Europeans, dairy products were very important. Some peoples prohibited the consumption of horses, dogs, or pigs, but for others, these were accepted items of consumption. A combination of grains provided the basic foods of the great majority of the earth’s people: rice, wheat, and millet in East and South Asia; wheat, rye, and barley in the Muslim world and Europe; various types of millet and teff in much of Africa south of the Sahara; maize for the peoples of Mesoamerica; and maize and quinoa (along with potatoes) in the Andes. The foodways of the world were not, however, static during this era; change occurred in almost all regions as incremental innovations in agricultural crops and technology occurred. The most spectacular changes occurred in the North American Southwest and Southeast, eastern Polynesia, the Muslim world, and Africa south of the Sahara. Mesoamerican crops—maize, beans, and squash—diffused northward to revolutionize the cuisines of the North American Southwest and the Eastern Woodlands; sweet potatoes from South America changed the cuisine of eastern Polynesia; the diffusion of Southeast Asian crops, par-

ticularly bananas, enriched the foodways of Africa south of the Sahara; and the Muslim world underwent an agricultural revolution as South Asian crops were added to the menu.

Popular cultures and high cultures expressed themselves in numerous genres of art, and we can know some of this through artifacts. Great public monuments are the most noticeable artifacts of the age: they were meant to be statements of the grandeur and power of institutions and ideas. The Classical Period of Mesoamerica and the Andean civilizations (ca. 100–900 CE) announced itself in numerous great pyramids and platform mounds. The same time period, which approximates the golden age of Mahayana Buddhism, witnessed the construction of numerous great Buddhist monuments: gigantic sculptures, cave temples, and pagodas throughout East, South, and Southeast Asia, such as the cave temples of Ajanta and Elora in India; the massive grottoes and hand-hewn caves at Longmen, Dunhuang, and Yungang in China; the now destroyed Buddha statues at Bamiyan in Afghanistan; and the great Javan Buddhist temple mound of Borobudur. The most impressive example of Christian monumental architecture during this era was the church of Hagia Sophia in Constantinople. Muslims constructed great shrines and mosques in many regional capitals of the caliphate. The Great Mosque of Damascus is a prime example.

Great public monuments are the most noticeable artifacts of the age: they were meant to be statements of the grandeur and power of institutions and ideas.

Most peoples exercised their artistic bent in pottery, and some non-literate cultures would remain enigmas without their clay artifacts. This is especially true of the Mochica, the North Peruvian culture of the era. In their exquisitely comic and often pornographic ceramic figurines, we can view their daily lives and sometimes their inner thoughts. The Chinese invention of porcelain, toward the end of the era, produced a ceramic that surpassed that of any other civilization and was traded throughout Afro-Eurasia. This became an expression of high-class culture everywhere. China was also the fount of many other things, the consumption of which was reserved to the elite of Afro-Eurasia. Tea and silk were two such items.

Painting and visual art during this era were not, except sometimes in Tang China, designed to be realistic but rather to convey a message. In the Christian West, the humanistic naturalism of the Greco-Roman classical age was abandoned in favor of art intended to be didactic, to convey a religious message. In the Muslim world, visual representation of people or animals was discouraged, but Muslim monuments and mosques were adorned with beautiful Quranic calligraphy. Chinese painting was more realistic, but artists during the Tang dynasty were less interested in faithfully representing objective reality than in representing the inner meaning of a scene.

In music, very little can be said for most cultures of the era. The music of Christian cultures that has survived the ages is mostly church music, which in this era was mostly noninstrumental vocal music such as the Gregorian chant. The more puritanical Islam disapproved of music of any kind, but the Islamic elite kept songstresses, sometimes free

but usually slaves, to entertain their guests. In the Tang dynasty, music and musical instruments were ubiquitous elements of both popular and elite culture, but little of Tang music has been preserved except by traditional musicians of the imperial Japanese court. Tang dynasty musical instruments and musical compositions were discovered in the 1990s. Now, using reproductions of these instruments, Chinese musicians play Tang compositions in concerts at the Hubei Museum. In Africa south of the Sahara, music was characterized by drumming and elaborate call-and-answer vocalizations, but increasingly during this era, Indonesian music that utilized marimbas or xylophones was diffusing across the African continent from the Malagasy in Madagascar.

A truly comprehensive coverage of society and culture in the Era of Expanding Regional Civilizations would be impossible even in an encyclopedia of this scope, but the facets of the subject discussed here are some of the highlights.

—Wilfred J. Bisson

■ Introduction: Early Medieval Families and Gender— A Global View

In the early medieval age (300–1000 CE), the vast majority of the earth's population lived in patriarchal families, based in sedentary agricultural villages. These families were units of biological continuity, but they were also the basic units of economic production as well as the basic social and emotional institutions. The agriculturally based patriarchal family structure has shown remarkable endurance from at least the fourth millennium BCE until well into the twentieth century in the West. It is just now being challenged in much of the rest of the world. Most early medieval societies were patrilineal, tracing descent in the male line, but some, especially in West Africa and among the western Bantu, were matrilineal, tracing descent in the female line. With only a few minor exceptions, all were patriarchal, with males dominating economically, socially, and politically.

Male dominance of society and politics was not as firm among the pastoral peoples or among the stateless agricultural villagers, such as the ancestors of the Cherokees and Iroquois. Women in those societies often exerted decisive political power. For gender relations among the northern hunters, the hunters and gatherers of the world's

forestlands, or the foragers of Australia, anthropologists have given cloudy and often conflicting testimony. Perhaps more light will be shed on that subject in the future.

In all societies, the lot of women was to marry at an early age and to bear children at intervals of two to three years. In addition, women did much of the basic work in most early medieval societies, producing, processing, and cooking the food; weaving textiles and fabricating clothing; and caring for the children, the elderly, and the men. Romantic love was not a consideration in marriage; rather, it was looked on as a sinful luxury of the wealthy elite. The highest virtue for any woman was to perform her familial duty as a wife and mother and to do as her father and husband told her.

Some women, especially in Buddhist and Christian societies, avoided this matrimonial fate by becoming nuns. Convents, where nuns dwelt, were women's worlds, where women could and did exercise power.

In most early medieval societies, prostitution existed. It was probably more prevalent in East and South Asia than in Christian Europe or the Muslim world because East Asia, particularly

China, was more urbanized, and in the West prostitution incurred a greater social stigma. In China and other parts of East Asia, female entertainers were often also prostitutes, and some of them had relatively high social prestige, as had the hetaerae of fifth-century BCE Greece. In India, temple dancers were often also prostitutes, and prostitution was a recognized legitimate profession. In the Muslim world as well, certain classes of entertainers, known as songstresses, were sometimes prostitutes.

Childhood was a dangerous time of life in early medieval societies. Child mortality, by any modern standard, was appallingly frequent. Although most women were pregnant for much of their lives between puberty and menopause, many of these pregnancies were terminated in stillbirths. Induced abortions were not disallowed by the religious or political authorities and were resorted to especially when it was feared that the baby would be abnormal or handicapped. Infanticide was also practiced in many societies, sometimes for economic or social reasons. Death in childbirth may have been one of the most frequent causes of female mortality in many early medieval societies. Early medieval children shared their lives intimately with domestic farm animals, and farm animals have notoriously been one of the most prolific sources of childhood diseases. Children born into early medieval families had less than an even chance of living to adulthood.

Children were not pampered in the majority of early medieval agricultural societies. Corporal punishment was normal in rearing children. Children were allowed free play for only a few brief years in early childhood; as young as five, they were inducted into the labor force. If they were children of peasants, they were given agricultural or domestic work. In elite families, children were given different tasks, sometimes being educated by stern tutors or being trained in the martial skills. Sometimes children were employed as singers or servants of the warrior classes.

The lives of adult men were, on the whole, easier than that of early medieval women. In agricultural societies, men usually did the most physically demanding work, such as plowing, sowing, and most of the work in reaping, but they also often had the best food available for

the farm family. In wealthy elite families, some men could be wastrels, but most elite men were engaged in occupations such as governmental administration, military command, religious and monastic pursuits, or mercantile affairs. The great advantage that men had was that they controlled the major institutions of societies: the armies, the governments, the churches, and religious institutions.

Gender and Matrilineal/Patrilineal Social Relations in East, Central, and Southern Africa

In postclassical East, central, and southern Africa, men and women were viewed as equals. Both gender and age were factors in the division of labor, but key elements of social hierarchy were based on seniority, not gender. Men's jobs were not considered more important than women's jobs. In Bantu-speaking societies during this period, women controlled the technology of agriculture, pottery, house building, and food preparation, while men herded the animals, carved wood, and smelted iron and were responsible for protection. At the beginning of this era almost all East, central, and southern Africans lived in subsistence-based economies. Within these economies women controlled the bulk of the food production and preparation. Thus, it is not surprising that women enjoyed economic power and often held positions of leadership.

Since there was an abundance of land and no concept of private property, labor was key to survival. Low population density and a constant shortage of laborers contributed to making motherhood the most powerful social institution in this area. Infant mortality was extremely high; therefore, the need both to reproduce and

➤ NO PATRIARCHS IN BANTU-SPEAKING SOCIETIES

Women were not oppressed as women in Bantu societies for at least the last 2,000 years prior to colonialism. Seniority, not gender, determined status, and older women had political and economic control over younger women and younger men. The gender equity of Bantu-speaking peoples challenges the widely accepted historical hypotheses that the oppression of women is universal and has always been a part of human existence. African women were leaders and had important status, especially as mothers.

—Christine Ahmed-Saidi

to protect babies became essential to the survival of these people. Under these conditions, it is not surprising that by 300 all Bantu-speaking societies were matrilineal.

Clan membership was calculated through the mother's bloodline, but matrilineality was not just a method of inheritance and social affiliation; it was also an ideology. Matrilineal societies tended to be decentralized, and surpluses were widely distributed to distant relatives. The private accumulation of goods was discouraged. The basic social unit of matrilineal societies in the later part of this period consisted of a grandmother, her married and divorced daughters, and their husbands and children. Female initiation rites were the most important ceremonies in these societies, although many communities still celebrated male initiation.

For a man to marry in a matrilineal society, he had to work for his future mother-in-law for several years and show that he could father children before he was accepted fully as a husband. Marriage was a process that started at the marriage ceremony and ended when mother-in-law avoidance rules were lessened, usually after years of labor and several children. In matrilineal societies during this period, the mother-in-law was highly respected and was often able to control the labor of young males in her own family.

While marriage was considered very important for the raising of children, the social category of wife was relatively unimportant. This was probably also true 5,000 years ago since we

can reconstruct a proto Bantu word, *yadi*, to signify a life stage for a young woman from puberty to her first pregnancy. In other words, a young woman would enter puberty and be married yet was still considered a *yadi* until the birth of her first child, when she became an adult. In this society, motherhood rather than marriage was the event that signified a girl's entry into adulthood. Men also were considered adults only after they had fathered a child.

During this period some societies began shifting from matrilineal to patrilineal descent. In patrilineal social organization inheritance and clan membership were determined through the father's bloodline. Patrilineal societies differed from matrilineal societies in that they tended to create corporate kinship organizations that controlled female labor to a great degree. Polygamy was much more common in patrilineal societies, and since women produced most of the agriculture, husbands with several wives could control agricultural surplus. Private accumulation of goods was also possible within a patrilineal society. Wifedom in patrilineal societies became a more important institution because a young man could not marry unless his family had presented the future wife's family with goods, cattle, or other valuable items. Women lost some of their independence as young wives but retained their role as sisters in their own clans. In both matrilineal and patrilineal societies young men and women wielded little power, gaining status through parenthood and seniority.

After 500, many cattle-keeping peoples in East, central, and southern Africa changed to patrilineality. In societies that depended on cattle raising, chiefs were able to command younger male support by inflating the amount of cattle needed for marriage. The young men were forced to work or fight for the chief since he controlled distribution of cattle. Bantu-speaking peoples in the Nyanza (Lake Victoria) area of the Great Lakes by 1000 had become patrilineal and were socially organized to the extent of having a king. Yet in most of the centralized Bantu-speaking societies the queen mother and other royal women, especially when united, could command more political power than the actual ruler.

Not all cattle-keeping peoples abandoned matrilineality. The Botatwe of east-central Africa

retained matrilineality even though they adopted cattle by 800. The Herero of southwestern Africa raised cattle, but they relied on a dual lineage system with matrilineal descent for political leadership and patrilineal descent for cattle ownership. Their dual lineage may in part reflect the heavy Khoisan influence, since Khoisan speakers tended to organize along a dual lineage system. The Lovedu of southern Africa were patrilineal cattle keepers, but political leadership lay in the hands of the rain queen.

In east-central Africa, Bantu-speaking peoples had consolidated their matrilineal belief systems into a matrifocal, or mother-centered, system. God was no longer a distant figure but instead was a nurturing force like a mother. The most important ceremony was the two-part female initiation ceremony celebrating a young woman's *yadi* life stage. The first ceremony was when a young woman reached puberty, and the second was when she felt the movement of her first child. In this underpopulated land with limited soil fertility, motherhood and female sexuality were highly celebrated.

By 1000 the majority of Bantu societies were still matrilineal and decentralized. Women retained their equal status in these communities well into the nineteenth century. Even within patrilineal societies women remained independent players. Within the kingdoms and states of the next historical era, common women began to have their positions challenged. Yet even within these kinds of politics the women of royal and chiefly status still acted as power brokers.

Families and Kinship in Tang China

The family in China was viewed as a microcosm, a state in miniature, with the father as the ruler and other family members as his subjects. The family was thus the standard social unit, while the individual was of little importance. The family was responsible for its members as well as for activity in political life. The state and family were further linked in that it was the responsibility of the family to raise filial sons who would be obedient and loyal to the ruler. The study of the family in general is difficult in early China because the vast majority of the evidence is for the elite classes. Little direct evidence for nonelite classes exists prior to the nineteenth century. Therefore, the following must be viewed as a discussion of the elites of China and not China as a whole.

The statement is often made that the Chinese family was always patriarchal, patrilineal, and patrilocal. Despite their common use, these concepts are only generalities. As was common in patriarchal agrarian societies, the family was headed by the eldest male. He was an autocrat, having the power of life and death over family members. However, as the head of the family, he himself was ruled by a reciprocal code that made him responsible for the family members. After the father, the next levels of authority were the sons, in terms of power ranked from eldest to youngest. Within generational cohorts the elder members took precedence over the younger members. This can be seen in the complex network of nouns in the Chinese language that describe one's relationship with others in terms of what one calls them.

In theory families were patrilineal, with all inheritance passing to the sons through the father. However, patrilineal ideology was more fluid and was frequently compromised. By the time of the Song dynasty the patrilineal nature of the family relaxed somewhat as improving economics inflated the dowry prices for women.

THE AFTERLIFE MARRIAGE

The family was considered so elemental in Chinese society that arrangements were often made for the nuptials of those who died before marriage.

Since the otherworld was believed to be essentially the same as this one, the marriage of those in the afterlife was seen as an act of compassion. In this way the needs and wishes of the deceased could be met. Like marriages in this world, the afterlife marriages were arranged by families, and proper etiquette for such arrangements had to be followed. There were even models for prayers to congratulate the bride and groom. The following is from documents found at Dunhuang.

Sample prayer to be recited by the groom's father during wedding ceremonies for afterlife couples:

"So and so, I hereby inform you: You died at a young age and thus did not fulfill the meaning of the husband and wife relationship. You sleep alone in the dark world and lack the intimacy of man with woman. Just as living people long for companionship, the dead fear loneliness as well. Unexpectedly, so and so's family had a daughter who also just passed away like an autumn leaf. We sent a betrothal for you so your souls might meet. We selected this auspicious day for the rite of your union. We also set out an offering next to your shrine tablet, furnished with all kinds of delicacies. Please send your spirit down to the banquet and eat the meal."

In many cases families wanted to protect their investments, and women began to inherit in some cases.

Chinese families were also patrilocal and were grouped into clans consisting of all families with the same surname living in a particular district. This descent from a common ancestor became the focus of group rituals.

Extended families developed in Neolithic times as a way to survive and as a way to gather

and preserve wealth within the family. However, the philosophical basis for the family structure came from the writings of Confucius. Confucian reverence for filial piety meant that family members were at the beck and call of all older or more hierarchically superior members of the family. Parents and grandparents held the key positions. This was made easier because all members of the family lived in the same compound. The ideal situation was to have four generations under one roof, although this rarely happened. Reverence for older family members extended to the dead through the practice of ancestor worship. Since only males could make the sacrifices and perform the rituals for the ancestors, it was critical for the family to produce male heirs. These rituals for honoring the ancestors helped to bind the family together.

Large families are thought of as the norm in China; however, they were more often the exception. Large families were expensive. They meant dowries for the daughters and marriages for the sons. Peasants generally limited their families to six members at the most. Since this could include grandparents and daughters-in-law, the number of children must have been far fewer than the fabled "100 sons." Another factor that limited family size was the practice of dividing the land among all surviving sons when the father died. This practice began to be phased out during the period between the fall of the Han dynasty and the rise of the Sui dynasty.

Families were tied together by ritual. The survival of the family as a unit depended on having sons to continue the ritual sacrifices for ancestor worship. Survival also depended on preserving or increasing family landholdings so that all the sons could marry and have and support families of their own.

After ancestor worship, the most important family ritual was marriage. The selection of marriage partners for the family's children was controlled by the fathers, which could help explain the traditional animosity between daughters-in-law and mothers-in-law. Marriage was considered so important that parents of children who died single often arranged posthumous marriages for them.

The father contracted with a matchmaker, who was almost always female. She interviewed

the prospective brides and their mothers and then reported back to the groom's father. Female matchmakers were specially prized, as they could actually examine the bride for health, beauty, and so on, and matchmaking was one profession that women could enter without stigma. Choosing the proper mate for their child was especially important since marriages were between families, not individuals. Males were allowed to marry at age 14 but were usually much older. Females were of marriageable age at 12. The state was not involved in the marriage process unless there was a question of fraud, such as lying about the health, age, or morality of the bride or groom.

Once the prospective new family member was chosen, a contract was drawn up by the groom's father or the eldest family male and sent to the bride's family. Her father or the senior male of her family signed and returned it. The bride and groom were rarely consulted about the choice, and they rarely disagreed with the family's decision. Next, symbolic gifts were exchanged between the families. A gift of glue and lacquer might represent cementing the relationship. A gift of silk floss to the bride encouraged her to be meek and remember her place. After the arrangement of the marriage settlement, the marriage was sealed in a ceremony in which the couple bowed to ancestors and to the groom's parents.

Brides left their family homes to live with the groom's family, except in the case of grooms who were marrying up socially. In that case the groom moved into the bride's house. In later times brides severed connections with their natal families, but new research shows that before the Song dynasty married women played important roles in their natal families. Men who through political connections did well were supposed to share the advantages of these new connections with their affinal relations, especially those of married daughters. High-ranking maternal grandfathers often helped find positions for grandsons, and persons connected with the imperial family might even receive help from the maternal grandmother.

The law allowed for severe punishments for disrupting the harmony of the family. Fathers had the power of life and death over their wives and children. A father had the right to beat an

errant son to death if he so chose. If a son struck his father, the son could be beheaded. A wife who struck her husband would be beaten. A man who hit his wife would not be punished unless she was severely injured. Female adultery was far more serious than male adultery.

Early Medieval European Family

As in all societies throughout history, the family was the basic building block of late antiquity and early medieval society. The structure, definition, and size of families, however, evolved over time as the nature of society itself changed. That notwithstanding, the family remained an important institution throughout the period, even when the ascetic and monastic movement emerged and challenged conventional family life. Indeed, during the fourth to eighth centuries the family became an even more stable and important institution, and the evolution of marriage customs in the same period further reinforced the structure of the family and its importance in society.

According to Tacitus (ca. 56–ca. 120), the Roman moralist and historian, the premigration Germanic family was a tight-knit unit. He notes that mothers nursed their own children who often ran about naked and dirty, which allowed them to develop their bodies fully. Children were raised with minimal pampering and were only married once they had reached maturity. Adultery was rare, according to the Roman writer, and women caught in adultery were severely punished. The importance of the marriage vow and of family was taken very seriously, and women were expected to share in their husbands' labors

in the field and even in war. Not only was the nuclear family bound closely together, but the extended family was as well. Members of the family were expected to participate in family feuds, and nieces “are as highly honored by their uncles as by their own fathers” (118). This idyllic picture, which may have more to do with Tacitus’s desire to criticize contemporary Roman mores than any desire to reveal the reality of the Germanic situation, bears a grain of truth; the close bonds of the family in later barbarian Europe supports the portrayal in Tacitus of the premigration German family.

The family of the early Middle Ages was shaped not only by premigration Germanic tradition but also by Roman and Christian traditions. Indeed, as the various Germanic peoples settled in the former western empire, they came into contact with Roman legal traditions and Christian views of the family. According to Roman law, the father was the *paterfamilias* and had complete control over all his children as long as he lived. Although the life-and-death authority once exercised by the Roman father—according to legend, the founder of the Republic, Brutus, executed his own son for the son’s betrayal of the city—no longer was in force by the fourth century of the Common Era, the father retained significant power in the family, which reinforced Germanic tendencies in that regard. Christian teachings emphasized friendship and charity within the family, and Christian theologians strove to define the importance of marriage, creating the monogamous traditions that shaped marriage and the family by the eighth century.

In the early Middle Ages, however, the family was in a somewhat fluid state owing to the various marriage customs of the Germanic peoples. Indeed, loose marital practices allowed for a much broader definition of family than that of a mother, father, and children. Polygyny was practiced, at least by kings and nobles, into the eighth century, and all children were welcomed by their father; illegitimate children even shared in the inheritance. Indeed, Charles Martel was born to an illicit union and rose to command the Frankish kingdom in the early eighth century. And the history of Gregory of Tours is filled with the multiple marriages of the Merovingian kings

and their numerous concubines and children. This situation changed, however, under the Carolingian dynasty, which sought to promote monogamous marriages and thus stabilized family structure.

The family was also an economic unit. Marriages involved exchanges of often significant amounts of movable wealth and property and were arranged to promote the economic interests of both sides. The family household was the center of much economic activity. It was there that the basic economic activities of the period took place. Cooking, brewing beer, baking, and spinning were done in the home. Women also prepared candles, soap, and other necessities for the family, and animal husbandry and farming were performed at this level. And all members of the family participated in the economic activity of the household. At the head of the household was the father, and all members of the family were subject to his authority.

It has been customary to maintain that children were raised with little sentimentality or affection. Indeed, it has been suggested that the chances for the survival of children were so slim that it is likely that little attention was paid to them before they were seven years old or so and that even then they were treated roughly. Corporal punishment, as contemporary legal codes reveal, was practiced; fathers could sell their children into slavery; and there is even some indication that infanticide was practiced, as it had been in ancient times. This view, however, has been challenged, and anecdotes from the histories of Einhard, Gregory of Tours, and others suggest that there was a great deal of family affection in the early Middle Ages. Charlemagne, for example, loved his daughters so dearly that he would not let them marry and always kept them by his side. He would go riding and hunting with them and loved them and the illegitimate children they had with members of the royal court. Moreover, even the most ferocious Merovingian queens, Brunhilde and Fredegund, revealed their maternal sides quite clearly in the protection of their children. They struggled mightily against each other to promote the interests of their sons, and Brunhilde wrote to the emperor tearfully seeking his aid in protecting her daughter, who had

been lost in North Africa. The situation of children was also improved by the reforms of the Carolingian dynasty, which strengthened marital practices and family structure.

Gender in Dar al-Islam

One of the major debates of the early Islamic period concerns the impact of Islam on women's status and gender roles. Some scholars maintain that women were better off before Islam, citing pre-Islamic practices that allowed women to have greater independence than they did after the arrival of Islam. Others claim that Islam advanced women's status, emphasizing innovations in the Quran (Muslims' sacred book) that improved conditions for women. Both arguments raise important points. Unfortunately, there are so few extant sources for the period in question that neither perspective can be verified absolutely. However one sides with the debate, it is unambiguous that the early Muslim community had far more liberal attitudes toward women compared to their descendants,

the Umayyads (661–750) and the Abbasids (750–1258). But Islamic legal discourses were developed during the later periods; therefore, misogynist perspectives were enshrined in many aspects of Islamic law.

Women in some cultures of the Middle East probably had more autonomy before than after the spread of Islam. Women in pre-Islamic Arabia actively participated in many community affairs, including war and religious activities, and women could initiate marriage and divorce on their own terms. It is not clear which types of marriages were most prevalent, but polyandry (in which a woman may have several husbands), matrilineality (in which descent is determined by the female line), and matrilocality (in which married couples reside with or near the bride's mother) did exist in addition to male-centered marriages.

Islam certainly did not introduce patriarchy or misogyny to the Middle East, and it actually brought a number of new protections to women. The Quran gave women inheritance, dowry, and maintenance rights; it also sanctioned women's right to own property, banned female infanticide, forbade levirate (forcing a widow to marry her husband's brother), and limited Muslim men to four wives. The Quran states frequently that all believers are equal before God; Muslim feminists today point to these verses to argue that equality of the sexes is consistent with the Quran's message of spiritual egalitarianism.

Despite these advances, many of the practices that Islam endorsed did restrict women's autonomy. Whereas the pre-Islamic period saw a variety of practices, Islam limited options and tended to sanction those favoring men. Women were limited to one patriarchal form of marriage, divorce greatly privileged men over women, and the husband's family was given custody rights over the wife. Women no longer could initiate marriages or divorces, and their legal testimony was half that of a man's. Initially, the practices of veiling and seclusion were practiced only by the Prophet's wives. Such customs long predated Islam in parts of the Mediterranean and Persia and only became common among the elite in Muslim communities after Islam spread to these areas.

➤ KHADIJA AND AISHA

One can examine the question of Islam and gender by comparing two of Muhammad's wives. Khadija illustrates women's pre-Islamic status, and Aisha demonstrates changes that Islam instituted. Khadija, 15 years Muhammad's senior and his first convert, was a divorced business-woman for whom Muhammad worked when she proposed marriage. Khadija neither secluded nor veiled herself, and their marriage was monogamous. Aisha was nine years old when her father married her to Muhammad. During Aisha's marriage, she and Muhammad's other wives began new customs of seclusion and veiling. After Muhammad's death, Aisha was engaged in politics until she led an unsuccessful battle. Later she became an important authority on the Prophet's sunna (practice), which is a basis for Islamic law.

—Elizabeth Brownson

Muhammad the Prophet visiting his first bride, Khadija. This painting illustrates a level of gender equality in the early Islamic world, which declined as the centuries passed. (Snark/Art Resource, NY)

Women's status, like other social dynamics, varied by place and time within Arabia and the greater Middle East. It is also useful to note that many values attributed to Islam are actually rooted in preexisting cultural traditions. For example, the idea that female chastity is necessary to preserve the family's honor is a cultural custom, not an Islamic law.

Gender in China

"Men plow and women weave" (*nangeng nü-zhi*). Daughters are born "facing out [away from the family]." These sayings are often used to describe the status of women in early China. This

status had much to do with Confucian ideals of piety, which included loyalty, filial piety, integrity, and righteousness. It was also connected to the hierarchical nature of Chinese family structure, code, and cosmology. For Chinese the female essence was yin, which comprised all things dark, weak, and passive. The male essence was yang, or everything that was light, strong, and active. Since yin and yang must balance, it would stand to reason that both genders should have equal complementary status. However, generations of male writers supported the idea that women were inferior and should stay that way. Such ideas developed into the patterns of passivity that were expected of women. Girls were subordinate to their brothers and fathers, wives to their husbands, and mothers to their sons, and models for women from literary sources were familial and passive.

Despite this common view, Chinese women should not be examined as a monolithic whole. Many factors affected women's actual roles as opposed to their models, including age, marital status, ethnicity (Han Chinese vs. non-Han), family power and status, and location. Older women had more power and freedom than younger ones. The role of the daughter-in-law was far inferior to that of the mother-in-law. The position of unmarried women was extremely vulnerable. Han Chinese women might attempt to model themselves more closely on Confucian ideals, but Confucian notions of the husband's superiority were not incorporated into laws in the north of China until the end of the Six Dynasties period. Elite women often fit more closely to the models, although even here there are notable exceptions. Women of the peasant class were required to work, and their ability to do so was considered in their selection as marriage partners. Wives, daughters, servants, and mothers all had different roles and were treated in different ways. Models for female behavior, such as those written about by Ban Zhou and others, placed women in inferior positions where they were universally subordinate to men. Some historians have taken these models as the literal truth, but they were meant as guidelines and not as reports on actual conditions.

Early writers on women in China, especially Western writers up to the 1980s, have considered traditional Chinese women as among the

Figurines of women performing various domestic duties, Tang dynasty, 618–907 CE. (Art & Archaeology, Inc./Corbis)

most oppressed in the world. Many of these studies failed to take into consideration the variables discussed above or had mapped the situation in nineteenth-century China onto earlier periods. In addition, much of the surviving material from earlier times dealing with women's roles was more about how men wanted women to behave rather than how women really acted. Current research shows that real-life women had more freedom in earlier Chinese history, but it also shows that the movement toward total subjugation began early.

Confucianist thought stated that the sexes should be kept separate and emphasized man's superiority over women. Ban Zhou repeated the admonition twice in her work that women should be quiet and self-restrained and not fond of playing or laughing. Although these norms were meant to apply to all women regardless of social status, the ability to work was a necessary trait for wives of the lower classes.

Punishments for women were based on ideas of filial piety and the double standard. Chinese family law shows that a wife who struck her husband could be beaten; however, a man who hit his wife would not be punished unless she was severely injured. Female adultery was considered far more serious than male adultery.

Chinese life was divided into spheres of influence, as is shown in the saying above on women's roles as weavers. All internal household affairs were managed by women. Anything

THE ANALECTS FOR WOMEN

The Analects for Women is especially interesting because it was written by the Tang scholar Song Ruoxin and her sister Song Ruozhao and was about Confucian values written by and for women. It applies these values to everyday activities, making it especially practical. This selection is from *Book Two: Learning to Work*.

“A woman should learn women’s work. . . . Choose silk threads for the warp and the woof to turn into bolts of silk cloth. Keep yarn on spools and thread on bobbins. With fine silk, ramie, hemp and coarse fiber you will have a lot to weave. These you can either sell or keep for your own use—making shoes or socks, using the thread for embroidering, mending, and basting; you should be able to do everything. If you can follow these teachings you will have no worry about coldness; when the cold comes you will be leisurely and dignified, worrying neither about clothes being torn, nor about your family being poor.

Don’t learn from those lazy women, who are petty and foolish and not eager to do women’s work, who don’t plan for spring or autumn and who sew brusquely and are attacked by others. When they marry, they bring shame on the new family. When clothes become torn, they rob Peter to pay Paul [‘tear down the east wall to cover the west’], are pointed at, and scornfully laughed at in the village. I venture to exhort all women to heed the words above.”

—Rebecca Wendelken

Robin R. Wang, *Images of Women in Chinese Thought and Culture: Writings from the Pre-Qin Period through the Song Dynasty* (Indianapolis: Hackett, 2003), 330.

outside the domestic sphere was the realm of men unless the women were peasants, and then they were expected to work in the family’s fields. Women had charge of household servants, childbirth, and raising children including their early moral training, daily household chores, control of the daughters-in-law and her husband’s concubines, and making sure that the correct rituals were preformed to propitiate domestic deities dealing with the household. Ancestor worship

rituals were the prerogative of the males, but the wife was in charge of preparing the rice for the rituals and therefore had to be free of blemishes. One of her main duties was to produce sons, and if she did not, she could be divorced or her husband could take one or more concubines.

Despite the admonition that women should be obedient to parents before their marriage and to parents-in-law after marriage, women’s filiality toward their own parents was not transferred to the husband’s parents until the Ming dynasty, and then only slowly. The role of mother-in-law gave women a position of power.

Beyond the realm of Confucian writing, women appear as different creatures. Women in poems are sometimes described as working as weavers or tea pickers. Tea picking was more physically demanding and was done outdoors.

In poems, tea pickers are shown as working as hired labor and as overworked by their bosses. However, they also are romanticized. Upper-class women picked tea as a pastime, rather like Marie Antoinette and her ladies played at being milk maids.

Women in northern China were responsible for the manufacture of one of China’s most famous and lucrative products: silk. Women and children in the countryside raised silkworms and reeled the yarn, processes that were both time- and labor-intensive. The yarn was sent to the cities, where it was woven by male artisans. Peasant women also grew and prepared ramie for weaving.

In Ban Zhao’s work, *Lessons for Women*, she states that women should be educated because it helped to cultivate their qualities of intelligence, moderation, and gentleness. Despite this, most women probably received little if any education. A few women, mostly from scholarly families, were educated and gained fame as poets and writers, such as the poetess Li Qingzhao. But since the object of Chinese education was to take the imperial examinations and women were not allowed to do so, there was really little point in educating them. However, by the Song dynasty, perhaps in reaction to the greater availability of books but also due to rising economic conditions, many women were learning to read and write.

Religions sometimes offered women an alternative life. When the daughter of a princess took

vows as a Daoist priestess in the eighth century, the court remodeled her mansion into an abbey. This was, of course, the upper class, and such possibilities were closed to commoners and peasants. Buddhism, with its ideas of universal salvation, appealed to women. The first Buddhist convent in China was established in 312 CE. Buddhism placed women and mothers in a relatively high position. However, Chinese translations of Buddhist texts over time replaced the “equal” words with “subordinate” ones, mirroring Confucianist thought. For example, “Husband supports wife” became “Husband controls his wife.” Courtesans and official entertainers registered with the government.

In the Tang dynasty women could be quite active, playing physical games such as polo. Even women of the court such as Empress Wu and Yang Guifei played this game. Women were also the principal performers of music during the same period.

By the Song dynasty there is more information available on women from a wide variety of classes due to the development of printing. These women were not entirely confined to the home, and many had occupations such as midwives connected with women. Buddhist nuns taught girls and women in upper-class homes, widows ran inns, and serving girls ran away from abusive masters.

The improving economy in the Song dynasty led to higher dowries. Women began to have control over their dowries, and their legal claims to property improved, if only for a short time. Neo-Confucianist writers such as Zhu Xi emphasized the importance of female subordination and segregation and their duty to conform to rigid gender roles. They favored permanent divisions in the home between men’s and women’s quarters. Women were encouraged to be free from jealousy, even if their husband took concubines, and to be faithful to their husband’s family even after his death. Confucianism became an excuse to subjugate women. This helped to change the ideal of beauty away from more athletic women to the more delicate. Women again veiled their faces in public and rode in sedan chairs through the streets rather than ride on horseback as they had during the Tang. Foot binding, which began during the

Tang dynasty, became more widespread, limiting women’s mobility.

Western Concepts of Masculinity

Europe in the early Middle Ages was a male-dominant culture in which masculine traits were universalized as ideal human traits. The same patriarchal system that repressed women, however, also forced men to conform to explicit

Saint Guthlac parts from his troops, from the Guthlac Roll, East Anglia, about 1210. Guthlac was the epitome of medieval Europe’s two ideals of masculinity: first, the warrior for Christ, and then, the ascetic holy man. (The British Library)

► THE CLASH OF MASCULINITIES— SECULAR AND SACRED

Early medieval Christian authors had ambivalent feelings about the warrior culture they depicted in their writings. Many had genuine admiration for men of courage and honor, but they rarely passed up an opportunity to moralize on warriors' worldly ways. For instance, in *Beowulf* (the poem dates from around the year 1000, but the extent to which it represents an earlier oral tradition is still fiercely debated), the old king Hrothgar tempers the celebration of Beowulf's victory by warning the hero not to succumb to pride, worst of the Seven Deadly Sins:

"Guard against evil, dear Beowulf, best of men, and choose the better, eternal gains. Do not be intent on pride, renowned warrior! The glory of your power is now, at one time; soon it will be that sickness or sword will deprive you of life, or fire's grasp or the sea's surging, or a sword's attack, or the spear's flight, or terrible old age, or the brightness of your eyes will fall and grow dim; it will be suddenly, warrior, that death will overpower you" (translation by author).

Although all the characters in this poem are pagans, here the poet speaks through Hrothgar to deliver this very Christian warning on the danger of pride and the transitory nature of the earthly glories sought by the warrior class.

cultural expectations. For ordinary men, being a man meant being a provider and head of the household, but for the aristocratic elite there were two additional models of manhood: the spiritual masculinity of the Catholic Church and the secular masculinity of the warrior class. A man who failed to perform his allotted cultural duties was deemed unmanly, a source of shame and sometimes a fate worse than death.

Attitudes toward masculinity (and femininity, since it is difficult to speak of one without the other) in the early Middle Ages were largely a product of classical views. Galen (130–200), the most celebrated physician of late antiquity, dominated the field of medicine for a millennium. Although he was a brilliant scholar (he proved, for instance, that arteries pump blood and not air), his understanding of human sexuality was deeply flawed. He maintained that there was a single sex for all human beings. This one-sex theory held that men were warmer than women, so their genitals could grow outside of the body, while women, naturally cooler, had those same sexual organs inside of the body. Women thus were inverted men. With the male body as the default human body, being a man or woman was not a distinction of biology but rather a distinction of social rank.

Early Christian theologians readily accepted the one-sex theory and augmented it with patriarchal values from classical philosophers (Aristotle) and Jewish thinkers (Philo of Alexandria). The church fathers of the fourth and fifth centuries, such as St. Ambrose (340?–397) and St. Jerome (347?–420?), taught that men were more rational and spiritual, while women were more lustful and beholden to materialism. They urged men to lead ascetic lives and to avoid women, whose licentious ways engendered sin. Even St. Augustine (354–430), who had more tolerance for sexuality (as long as it was confined to marriage), agreed with the other fathers that women were a dangerous temptation for men.

A holy man could escape the lure of female flesh by living as a solitary hermit or in a community of monks. Such spiritual masculinity involved resisting not only feminine wiles but also conventional markers of secular masculinity such as prowess and wealth. The Anglo-Saxon legends of Saint Guthlac (674?–714), for example, depict Guthlac as a renowned warrior and military leader who gives up his worldly life in order to live as a hermit in the wilderness. There, Guthlac battles temptation with the courage and heroic zeal that characterized his earlier martial persona. The saint's willingness to endure suffering highlights the key attribute of spiritual masculinity: the man's conscious emulation of Christ.

Expectations for secular men, meanwhile, involve three basic manhood scripts that can be found across time and throughout the world: impregnating women, providing for kin, and protecting dependants. As for the first, male sexual prowess was by no means in short supply; research indicates that male sexuality in this era could be characterized as aggressive and unrestrained. The role of provider can be seen in the prominence of generosity as a crucial manly virtue. While seeking riches was seen by the church as sinful greed, in secular society greed was found in hoarding, or keeping wealth out of circulation.

The third major male role is protection, a duty that fell chiefly to the warriors who made up the aristocracy. In most of Europe this class was descended from the Germanic tribes (Visigoths in Spain, Ostrogoths in Italy, Franks in Gaul, Angles and Saxons in Britain, etc.) that had been encroaching upon the borders of the Roman empire for hundreds of years and then filled the power vacuum left by the disintegration of the empire in the fifth century. At its most basic level, the ruling class of Germanic Europe was organized around male relationships. A lord would recruit other aristocratic men who provided him with loyalty and military service; in turn, he rewarded his men with treasure and status. This system, often referred to today as a *comitatus* (Latin for “fellowship”), a term used by the Roman historian Tacitus to describe such Germanic groups, was a precursor to the later feudal system, which added the exchange of land to these reciprocal responsibilities. The *comitatus* fostered male homosocial bonding (ties of platonic love) by means of rituals such as sharing the sacred mead-cup, giving and receiving treasure, and fighting side by side in battle. Men were expected to avenge the deaths of their beloved fellows, so feuding was widespread in the culture of warrior masculinity and was a source of great concern for church commentators.

Gender Distinction in Early Christian Centuries

During the first five centuries of Christianity, the leaders of what was to become the Roman Catholic Church developed a gender distinction based on the doctrine of original sin, which, according to Genesis, originated when Eve ate forbidden fruit from the Tree of Knowledge of Good and Evil in the Garden of Eden and in turn gave Adam the fruit to eat. This doctrine evolved as the Christian faith competed and interacted with the Jewish faith and pagan religions and as Christian leaders struggled against Roman imperial authorities. Ultimately, as Christianity evolved as an institution and became tied to the imperial government as the state religion, the doctrine of original sin established the notion of women as inherently morally flawed and served to marginalize women from political participation in the public sphere.

In the first century of the Christian era, the stories of what Jesus did and said were circulated among the populace in the Roman empire and interacted with diverse pagan religious traditions. Those traditions were, in general, socially and culturally patriarchal; they viewed women as a weaker gender than men, practiced taboos against women’s participation in official religious rituals during menstruation, and circumscribed women’s functions more or less to domestic spaces. These ideas and practices were based on the pagan understanding of women’s physiology and served various social purposes of agrarian societies. However suppressive the ideas and

➤ TERTULLIAN ON ORIGINAL SIN

Tertullian was a prolific Christian writer born in the late second century. As the first Christian author to write in Latin and the first to develop a number of theological concepts, his writings were highly influential on the development of Christian theology. The passage below illustrates Tertullian's interpretation of original sin, a view later affirmed by Saint Augustine, that served to limit the role of women in the Church:

"And do you not know that you are (each) an Eve? The sentence of God on this sex of yours lives in this age: the guilt must of necessity live too. *You* are the devil's gateway: *you* are the unsealer of that (forbidden) tree: *you* are the first deserter of the divine law: *you* are she who persuaded him whom the devil was not valiant enough to attack. *You* destroyed so easily God's image, man. On account of your desert — that is, death — even the Son of God had to die" (italics in original).

Tertullian, "On the Apparel of Women," in *The Ante-Nicene Fathers*, Vol. 4, edited by Rev. Alexander Roberts, Sir James Donaldson, and Arthur Cleveland Coxe (Buffalo, NY: Christian Literature Publishing Company, 1885), 14.

In this context, the new Christian faith offered women a liberating inspiration because the recorded acts of Jesus did not discriminate against anyone on the basis of ethnicity, social status, or gender. The early Christian movement eventually attracted women converts and encouraged them to spread the faith to their children and husbands, as well as to other women. The early Gospels, including many that were not later accepted as part of the New Testament, bore witness to Mary (the mother of Jesus), Mary Magdalene, and a few other women as the most humble and faithful followers of Jesus and the most patient and effective prophets of his messages. In his *Letter to the Romans*, Paul mentioned about a dozen female converts and activists. Among them, he showed his intention to give a certain female deacon Phoebe a "welcome worthy of God's holy people" and thanked her for "the help of many people, including myself." Most recent historical researchers have acknowledged that quite a few female prophets, patrons, teachers, and missionaries are recorded in the New Testament and suggest that some of them were ordained to fulfill a variety of religious duties in the same manner as their male counterparts during the time period when church structure was not formally institutionalized.

In the second and third centuries, charismatic leaders, activists, and scholars of Christian movements were able to gradually organize themselves and reach consensus on the components of the New Testament. In denouncing the Roman earthly kingdom and popularizing a new universal covenant with God, Church leaders began to provide their faithful followers with coherent norms to be observed on a range of theological and moral issues against what they perceived to be the pollutions of external pagan teachings and philosophy. Meanwhile, they also fought internal dissenters, or heretics, in their attempt to establish a Christian orthodoxy. Moral purity and ethical disciplines were therefore pushed to the forefront of their agenda.

At the turn of the third century, Tertullian (ca. 155–222), a convert to Orthodox Christianity in northern Africa (before his own conversion to Montanism), publicized a series of treatises in his battle against heresies, including the movement

practices were, the militaristic Romans never stopped venerating the duties of the Vestal Virgins by tending either the flames of their households' hearths or of the hearth in the House of Vesta to ensure the prosperity of their families and the empire. Women all over the empire continued to demonstrate their devotion to female deities, such as Isis in Egypt and northern Africa, where unique religious rites and celebrations were closely linked to crucial life experiences, such as securing a happy marriage, fertility, safe childbirth, health of family members, and deaths. Although norms reflecting different religious ethics and social expectations were in place to marginalize women's roles in public spaces, their voices and participation in the public sphere were never completely suppressed.

of Montanist apocalypse led by two women, that provides us with some insights into the moral concerns of the Christian thinkers of the time. On the one hand, he relentlessly advocated monogamy and blamed both men and women for their promiscuous affairs out of wedlock. In this respect, the upcoming Christian canons of marriage between consenting couples would become very distinguishable from marriage codes of other religions. At the same time, while affirming the virtues of virginity, chastity, modesty, and other ascetic values of his faith, he aggressively accused each and every woman of being Eve and the devil's "gateway." His condemnation went so far as to argue that on account of women's desertion of divine law, they ought to be held responsible for the death of Jesus and the fall of men, who were created according to God's image. Tertullian's rhetoric echoed the Greek myth of Pandora, the first woman as the bringer of evil, and therefore planted the roots of the doctrine of original sin. However, his derogatory remarks were made in the context of his concern about Christian women being persecuted for their appearances, since the people around him often mistook the public exposure of a woman for promiscuity. In general, Tertullian demonstrated in his various writings an absurd and ironic attitude toward women. Nevertheless, the discursive absurdity did indicate that the liberating spirit of the early Christian movement began to suffer from the arbitrary and abusive language of an ever more organized church.

Emperor Constantine changed the destiny of Christianity through his personal conversion in the early fourth century, which was followed by the establishment of Christianity as the imperial religion at the end of the century. The Christian leaders and thinkers were therefore no longer passive defenders of their faith for its survival but instead became determined and enthusiastic engineers for reconstructing the social and moral orders of the Roman empire, which they thought was suffering from internal decay. Throughout the empire, women were barred from priestly activities in the fourth century. In the western part of the empire, the ideas of integrity and universality motivated bishops in Rome to take more assertive actions to change

the religious attitudes and ethic norms of the people. St. Ambrose (ca. 338–397) labored to defeat heresy and to preserve the Church's doctrines. He promoted the belief in the virginity and purity of Mary as the mother of Jesus. Ambrose's goal was to protect the integrity of the Church, since the worship of mother goddesses and female prophets continued to be popular. St. Augustine (354–430) traced the fallibility of all humans to the original cause of Eve's seductive persuasion of Adam to eat the forbidden fruit. Eve poisoned Adam, and Adam passed in turn the inherited guilt to all of his descendants through sexual acts. Therefore, marital sexual acts with the purpose of reproducing children were necessary, but he condemned "irrational" desires for sexual pleasure, which he termed "concupiscence," because they prevented humans from loving God and holding, contemplating, and enjoying happiness in God. Although the reasoning apparently reiterated Tertullian's rhetoric, Augustine aimed less to repudiate any specific heresies of his time than to invent and elaborate a general and intrinsic moral flaw of the female gender and therefore founded the "universal" doctrine of original sin.

In the next two centuries, the Catholic Church and the Christian Fathers made a diligent effort to build a patriarchal government according to the Roman imperial model. On the one hand, they recorded with admiration a series of conversion stories in which both the Roman and the "barbarian" queens inspired their husbands to convert themselves and their peoples. They also applauded women who chose to live in the desert or in monastic celibacy and to devote their energy, wealth, and even lives to the mission of Jesus. On the other hand, they promoted the Augustinian doctrine of original sin. Successive campaigns to denigrate sexuality in general and exaggerate women's moral defects culminated in prohibiting women from holding any ordained mission in the Church. Women's role in the public sphere was diminished, and their rights to property and other benefits were reduced.

By the end of the fourth century, the slight gender liberation impulse of Christianity in the first two centuries was a thing of the past. From

the fourth century almost to modern times, Christianity taught that women were the source of original sin. Thus, the role of women in the Church as well as in European culture became more narrow and rigidly defined.

Gender and Politics in Byzantium

The modern understanding of gender and women in Byzantium, like many cultures from various eras, is fundamentally affected by the politics at that time. The political writings and elite primary sources shaped the notions of female power, imperial ideology, and gendered expectations of women, men, and eunuchs. The first and most revered imperial Christian woman of Byzantium was Helena (b. 248 or 250, d. 330 or 336), the mother of Constantine the Great. Helena was renowned for her piety, patronage, and visits to the Holy Land, and as Byzantium became Christianized, the fame and scope of Helena's building programs in Jerusalem also became exaggerated. For example, the late-fourth-century Church historian Eusebius boasts that Helena may have built over 30 churches in the city of Jerusalem itself, even though many of the churches and monuments attributed to her have been proven spurious. Moreover, Helena became the center of the creation of the imperial cult and was regarded as the ideal Byzantine Christian matriarch. She came to idealize the proper

and good empress, and sources for centuries afterward referred to many empresses as the "New Helena." Helena was depicted with her son and daughter-in-law, Fausta, on coins and in imperial art, but political intrigue caused the murder and damnation of Fausta (of which Helena was possibly implicated) and left Helena to reign gloriously as the dowager empress.

While Helena was glorified in Byzantium as the ideal empress, politics also shaped the understanding of a bad empress. Prokopios of Caesarea, the official historian to the emperor Justinian (r. 527–565), wrote an unofficial secret history of Justinian and his wife Theodora. The secret history of Prokopios, or the *Anekdota*, is especially critical and explicit about Theodora's vices, perversions, sexual proclivities, and general malfeasance. In spite of Prokopios's opinion, Justinian was deeply in love with Theodora and sought her counsel on important matters of state, law, and religion. As empress, Theodora was very involved in religious and charitable works and had many buildings and monuments commissioned throughout the empire. Yet Theodora's image is severely impacted by Prokopios's portrait of her in the *Anekdota*, a portrait that is in actuality an example of a stock literary form in the classical genre of invective.

In the eighth century, the empress Irene (r. 797–802) took politics into her own hands. Irene was married to the emperor Leo IV during the period of Byzantine iconoclasm (that is, two periods of Byzantine ecclesiastical and political history from 726–787 and 815–843 in which the use of icons depicting holy figures and the veneration of such icons were forbidden). At the death of her husband in 780, Irene ruled as regent for her ten-year-old son Constantine VI. During her regency, Irene swiftly promoted members of her family and powerful eunuchs to positions of political and military importance. Unlike the members of her husband's family, Irene believed in the use and veneration of icons, and she called the Seventh Ecumenical Council of 787, which was attended by 365 bishops from all over the empire, to reject the doctrine of iconoclasm. Although Irene is canonized in the Orthodox Church for returning orthodoxy and icon veneration, later iconoclastic sources of the ninth

THE THIRD GENDER—EUNUCHS IN BYZANTIUM

Eunuchs were an integral part of late Roman and Byzantine as well as Chinese, Muslim, and other medieval societies. In Byzantium, as in the Tang dynasty and the Muslim caliphates, eunuchs were sometimes employed in the highest level of imperial service. Although they themselves could never assume imperial title because of their corporeal incompleteness or bodily mutilation, they were often instrumental in promoting members of their families to the throne, the most notable being John the Orphanotrophos, who engineered the ascension of both his brother Michael IV (r. 1034–1041) and nephew Michael V (r. 1041–1042) as Byzantine emperors.

There is much interest in modern scholarship on the medical creation of eunuchs. The seventh-century physician Paul of Aegina stated that eunuchs were created either through crushing of a young boy's testicles or through removal of the testicles through incision. Prepubescent boys who were castrated exhibited all of the traditional traits associated with sexlessness, including high-pitched voices and smooth skin. Although castration could also occur after puberty, this case was much rarer than prepubescent castration. There is also interest in the debate on the origins of eu-

nuchs. There is much evidence that eunuchs were bought and sold in Byzantium in a servile state and were given as gifts from foreign courts to the Byzantine emperors. Yet there are also instances in which provincial Byzantine families castrated their young sons and then sent them to Constantinople, where they would attain the highest level of education and embark on lucrative careers. Symeon the New Theologian (949–1022), for example, rose to high imperial rank and was initiated into the court by his uncle, himself a eunuch and an imperial chamberlain. Nonetheless, Byzantine authors were revolted by and disparaging to eunuchs. The fourth-century historian Ammianus Marcellinus believed that they were “pale and unsightly because of their deformity,” and in the twelfth century Theophylact of Ochrid, as a favor to his brother, wrote a defense of eunuchs against charges that they were monsters and were known for their homosexuality and vice. Yet the significance and importance of this so-called third gender to Byzantium cannot be understated, especially during the reigns of Constantine the Great (r. 324–337) and Irene (r. 797–802), when eunuchs played crucial roles in imperial politics.

—Ruma Niyogi-Salhi

century malign her intentions as being purely political. Once her son came of age and reached majority, Irene, with strong support from powerful eunuchs and generals, still continued to direct the affairs of the empire, often at cross-purposes with her son. In 797 upon her orders, Constantine VI was seized, brought back to the imperial palace in Constantinople, and blinded, leaving Irene as the sole ruler of Byzantium. Irene chose not to remarry and instead ruled as *basileus*, or emperor, in her own name. She immediately struck gold coins depicting herself on both sides to emphasize this fact. In 801 or 802 an embassy was sent to Constantinople to contract the marriage of Irene with Charlemagne, who had just been crowned emperor in the West. These nego-

tiations, however, crumbled because of intrigue and political tensions among Irene's courtiers. Her reign ended in 802 because of a military revolt in Anatolia that eventually swept into the capital. Although Irene was noted for her peaceful restoration of icons, Byzantine chroniclers decried her cruelty and political manipulation of Byzantine politics.

■ Introduction: Social Order of the Early Medieval World: Class, Caste, Slavery

Inequality was a characteristic of nearly all societies in the early medieval age, 300 to 1000 CE. Elites and aristocrats dominated all agricultural and urban societies. The surplus produce of the peasants supported early medieval elites and aristocrats, while the peasants were the mudsills of society and performed most of the productive labor. Almost universally in agricultural societies (and most early medieval societies were basically agricultural), the dichotomy between the peasant wealth producers and aristocratic tribute takers prevailed. This was the case in the Andean civilization, in Mesoamerica, and among the North American Mound Builders; the Polynesians; many of the Africans south of the Sahara; and all of the high civilizations of East Asia, India, the Islamic world, and Christian Europe. Aristocrats and other elites were always a small minority, numbering in most societies less than 10 percent of the population. It probably required the surplus produced by 10 peasant families to provide even meager support for 1 aristocratic family. Luxurious support would require the surplus produced by 50 or even 100 or more peasant families.

Scholars in many early medieval societies (Christian Europe, Islamic lands, India, China, and others) likened a well-functioning society to a human organism, with the elite acting as the head, or thinking part, and the peasantry as the feet. It is significant that many early medieval people were commonly barefoot, and feet were often covered with mud, dust, and grime, while the head was elevated above the filth. The point of this was to emphasize the normally unbridgeable social gulf between the two classes.

While peasants, either enslaved or in a less extreme form of dependency, did most of the physical work, produced most of the wealth, and occupied the bottom rungs in early medieval society, the rulers, whether kings or emperors or called by some other title, were at the top. The social wisdom of the age treated them as a different and superior type of human, somewhere between heaven and earth. People sought the touch of a king as a cure for leprosy and

other normally incurable diseases. All of the major religions taught that rulers were appointed by God and had divine favor. Indeed, one of the earliest actions taken by a military man after a successful seizure of power was to seek divine approbation. Rulers endowed monasteries and other religious institutions and agreed to share the spoils of their dominance with the religious elite. Sometimes, rulers ordered their subjects to convert to a new religion. Examples are the conversion of the Rus to Christianity under Vladimir, the conversion of the Japanese to Buddhism under the Soga, and the conversion of the Uighurs to Manichaeism by I-ti-chien.

In many societies the aristocrats were largely a military caste, although in India, the land of formal castes, the highest caste was theoretically not the Kshatriyas (the warriors) but rather the Brahmins (the priests). But most of the Indian monarchs were warriors, with the Brahmins as their justifiers who sometimes manned the Indian bureaucracies. In China, the scholar bureaucrats were theoretically the elite class, but in times of troubles, such as the period of division between the fall of the Han and the rise of the Sui dynasties (220–589 CE), military men, often of “barbarian” origin and the Tang dynasty after An Lushan’s Rebellion (756), became the leading elite group. In western Europe (where the concept of aristocracy was defined) aristocrats were commonly horse-riding warriors, or knights.

In early medieval societies, the military and other secular aristocracies usually shared social prestige and wealth with a religious aristocracy. In India and Sri Lanka, the religious elite included members of the Brahmin caste but also high-ranking Buddhist and Jain abbots and other monks. In Southeast Asia, although there were a few Brahmins at the royal courts, most of the religious elite were Buddhist monks.

In China, from about 400 to 840 CE, Buddhist and sometimes Daoist monks were at the apex of the religious aristocracy, but after the great persecutions of the 840s, Confucian scholars began to acquire renewed prestige.

In Christian Europe, the Christian clergy not only monopolized positions of religious prestige but also composed almost the entire intellectual class as well as manning much of the bureaucracy of European states.

For Muslim lands, it was less easy to identify a religious aristocracy, since in orthodox Islam there was no consecrated clergy. Nevertheless, by the eighth century a class of religious scholars, collectively known as the *ulema*, filled the role of religious aristocrats.

Some scholars think that the scribes who carved or at least composed the glyphs on the Mayan monumental architecture were religious aristocrats. These scribes, in this view, were responsible for the Mayan Long Count calendar devised Mayan mathematics as well as for astronomy.

In some early medieval societies, social mobility from a lower class to a higher class was sometimes possible, but it was seldom easy. Most societies imposed hurdles to minimize social mobility. By the end of the early medieval period, class differences were becoming impossibly great in many areas of Europe as the feudal system was being elaborated. In China, the increasing insistence on scholarship had the effect of shutting out the lower classes, since they had neither the wealth nor the time required for the long years of study. In many cases, not even the acquisition of wealth was sufficient to open the doors to social mobility, but over generations wealth was often effective in minimizing social differences.

Almost all of our information about the social structures of nonliterate non-Eurasian societies is based on archaeological inference and, to a lesser extent, on oral history and mythology. Information from both of these sources gives little reason to think that social equality was widely practiced in any complex agricultural society. In Mesoamerica, monumental architecture and burial practices point to deep social chasms. Among the agricultural chiefdoms of North and South America, the evidence indicates societies dominated by "Big Men," served by commoners. And in Polynesia the chiefs lived like gods, and the mass of people lived much more meagerly.

—Wilfred J. Bisson

Peasants in Sui and Tang China

Nothing was simple about the lives of Chinese farmers during the Sui and Tang dynasties. Due to a scarcity of rain, especially in the north, farming itself was exceedingly difficult. What is more, farmers obtained land through a complex system that was dependent upon scrupulously kept household registers. To make ends meet, they had to market their produce, borrow money, rent land, and sometimes even flee.

Sui and Tang peasants were sophisticated farmers. Even though northern China is often subject to drought (with an averages of only 20–25 inches of rain per year), medieval peasants were adept at obtaining the land's highest possible yield. China's oldest complete agricultural manual, Jia Sixie's *Essential Techniques for Commoners* (*Qimin yaoshu*), which was written around 534–544 CE, furnishes an in-depth look at the variety of techniques and wealth of experience on which medieval farmers could draw. For example, whenever it snowed, farmers placed objects on top of the fields so that the snow with its moisture would not blow away. Jia also recommended that farmers plant a variety of crops so that no matter what the weather, some would survive. Medieval farmers also had access to a dizzying variety of grains and vegetables: Jia lists 86 different varieties of spiked millet and 45 types of jujubes. These knowledgeable farmers derived as much profit from the land as their technology would allow; in fact, northern Europe did not reach medieval China's level of agricultural productivity until the seventeenth century.

These efficient farmers were subject to a complex program of land allocation called the Equalization of Fields (*juntian*). In this system, which was in effect from 486 CE until the An Lushan Rebellion (755–763), all land belonged to the emperor, which his government lent in equal amounts to the people. Men between the ages of 15 and 60 received 80 *mu* (one *mu* equals 1/6 of an acre) of personal-share land (*koufen tian*) and 20 *mu* of inheritable land (*shiyetian*). Upon their retirement, the personal-share land was to be returned to the government for redistribution. The inheritable land, which

was to be used for planting mulberry trees, forever remained with the family. Based on the receipt of this land, farmers had to furnish a land tax (*zu*) payable in kind, a cloth tax (*diao*) payable in either silk or hemp, and a corvée labor tax (*yong*), which could be paid either in 20 days of unpaid labor service or in cash for securing a substitute. This system attempted to both encourage the cultivation of land and prevent its concentration in the hands of the few. Land could neither be bought nor sold. This system required close government supervision. Every year, the village headman was supposed to check each family's household register for accuracy; every three years, the census bureau was required to do the same.

This system was so complex that many scholars doubted that it was ever implemented. However, documents recovered in northwestern China indicate that it was, even in the empire's remotest parts. Nevertheless, the system did not entirely function as planned: the government usually gave far less land than prescribed, allotments were scattered, cultivators often rented out faraway parcels and tenant-farmed nearby ones, and household registers were falsified. The system collapsed because the government had progressively less land to redistribute, powerful families and monasteries concentrated land in the form of manors, and the An Lushan Rebellion made it impossible to maintain household registers. By 780 the Two-Tax system (*Liangshuifa*) replaced the Equalization of Fields. Under this new policy, peasants only paid taxes twice a year: in the summer they handed over a levy based on household wealth, and in the fall they paid a levy based on the family's landholdings. The central government no longer tried to keep track of household members; instead, each local government was given a quota based on the area's past productivity. Simultaneously, the government tacitly recognized the farmer's right to buy and sell land.

Although in theory taxes under the Equalization of Fields systems were relatively light, there were a number of other levies, such as miscellaneous local labor services. Under the Two-Tax system, the farmer's burden became even more onerous. Farmers tried to cope with the tax burden in a number of ways. One common solution

was to abscond. A squatting household (*kebu*) was not subject to the Equalization of Fields taxes. Under the Two-Tax system, even though a squatting household had to pay a household levy, it was free from corvée duties. Southern China was a particularly attractive destination because it was peaceful, land was plentiful, and the Equalization of Fields system was never implemented there. Another expedient was to become tenant farmers. By farming someone else's land, a family could avoid paying taxes, which the landlord would shoulder. In exchange, the tenant farmer would give his landlord 50 percent of his crop, certain commodities, and his or her labor services. The landlord would also provide him or her with seeds, farming tools, and draft animals, all at steep interest.

Farmers had many other strategies for coping, but these methods underscore how tenuous their existences were. To buy seeds or pay taxes, medieval peasants often borrowed money or grain from moneylenders. Lent money had to be paid back with 15 percent interest; one's possessions and land were collateral. Farmers who borrowed grain from monasteries were expected to pay 50 percent in interest. In other cases, borrowers would rent their land to their creditors; if the former defaulted, then the latter would take over ownership of the land. Although the law expressly forbade it, one might sell his or her children to a creditor.

Medieval peasants were knowledgeable about markets. Since some tax obligations had to be paid with cash, all farmers had to engage in market activities. As a result, many farmers raised cash crops that they would sell at local markets. The *Essential Techniques for Commoners* devotes an entire chapter to advice about commerce. Since farmers sometimes worked as wage laborers, they were also well aware of their labor's monetary worth. Even though most farmers were illiterate, they were all familiar with written documents. Contracts had to be drawn for almost any financial transaction no matter whether a person was purchasing a slave, hiring a laborer, borrowing grain, or even buying a shirt. After the contract had been read aloud, the participants would indicate their acceptance by signing their name or, if they were illiterate, making an outline of their finger joints.

In short, Sui and Tang peasants were sophisticated and market-savvy farmers. Despite their ingenuity, the crushing weight of their tax burden often led them to seek refuge by either fleeing or becoming tenant farmers.

Peasants in Early Medieval Islamic Lands

What must be noted about peasants in early medieval Islamic territories is that their situation was not significantly different from late antiquity when those territories were ruled by the Byzantine and Sassanian empires. The peasants, most of whom kept their own religion after the Islamic conquests, continued to pay taxes as they had before. The caliph Umar (r. 634–644) had forbade agricultural activity by his warriors, so the local peasants continued to cultivate the same land they had before. The fiscal administration of the Umayyad caliphate levied a head tax on non-Muslims (*jizya*). Muslim landholders were required to pay the land tax (*ushr*), so conversion to Islam did not guarantee one an exemption from tax. The peasants tended to be more conservative and less likely to convert than their urban counterparts.

The condition of the peasantry in early medieval Islamic lands depended on their location. In general, there is a dearth of information on the peasantry. Much of the peasantry of Syria and Egypt were non-Chalcedonian Christians; they had become alienated from the government of

➤ PEASANTS AND URBAN CENTERS

Peasants in the early Islamic period were connected to the major urban centers where they sold much of their agricultural surplus. They remained connected to these urban centers by the traditional water routes of the Euphrates, Orontes, and Nile and by the road network inherited from the Romans and maintained and expanded by the Umayyads. Thus, the distinction between rural peasantry and urban dwellers was not as extreme as it may have been in a much less densely populated area. However, in the later Umayyad period (684–750) the peasantry was transformed, as many of the peasants moved into the cities and converted to Islam and the lands were taken over by urban landlords.

—Benjamin de Lee

Constantinople and seemed to be more accepting of Islamic rule than their Orthodox counterparts in Palestine and North Africa. The Coptic peasants of Egypt were relatively prosperous, as they continued to cultivate the fertile banks of the Nile as they had for millennia before the Muslim conquests. They were largely Coptic-speaking people and were alienated from the Greek-speaking urban elites of Alexandria. They looked to the Coptic monks of the desert for spiritual leadership. Less is known about the peasants of the former Sassanian empire, but they also continued to cultivate the fertile areas of Mesopotamia as before.

In late antiquity, Syrian peasants had been relatively prosperous, and they used seasonal agricultural methods to maximize their yields from the land. However, this system began to collapse as landholders began to consolidate holdings. For whatever reason, the agricultural areas of Syria were not cultivated as much as they had been. The Persian invasions of the early seventh century further weakened the peasantry. Thus, for the Syrian peasants, Muslim rule in the early period meant an end to warfare, religious persecution, and rapacious landlords. The Syrian peasantry was able to recover somewhat, and lands that had been left fallow for some time were cultivated once again.

The Egyptian peasants also found a respite from warfare and a rapacious and sometimes

oppressive Byzantine religious and tax policy. As mentioned above, however, there was more continuity for the Egyptian peasantry. Developments, however, did occur in Egypt and elsewhere.

Irrigation systems were improved, and by the ninth century the water mill and the windmill were becoming more common throughout the Islamic world. By the eleventh century an Islamic agricultural revolution had taken place. New technologies had become widespread. New crops such as rice, sorghum, hard wheat, sugarcane, cotton, watermelon, eggplant, spinach, and many others ensured that the average peasant in the Islamic world had a much healthier diet than in most places. More land came under cultivation, and the growing season was extended. These developments lead to an overall improvement in the quality of life for the peasant in Islamic lands in the early medieval period.

European Peasant Society

Throughout the Middle Ages, the vast majority of the population lived in the countryside and worked in agricultural pursuits. In the early Middle Ages, approximately 90 percent of the population lived in the country, and even the largest cities were essentially farming communities. Normal life was rural life, and agrarian thought patterns dominated the culture.

Bondage to the manor defined a peasant's life. To understand medieval peasant society, one must first understand the manorial system, the economic and social milieu in which peasants lived and worked. Although free peasants resided in some areas, the structures and rela-

tionships of the manorial system offer a typical view of the lives of medieval peasants. In addition, manorial lords generally kept better records and left more evidence of their activities for historians to study than did proprietors who held land in other systems.

Manorialism originated in the agrarian conditions of the late Roman empire. During this period, elements of the Roman colonate system melded with Germanic ideas about lordship to form a unique political and economic structure. In early medieval, or classical, manorialism, the landholder's portion of the manor, the *demesne*, formed the center of the manor. The lord held and managed the manor and was assisted by slaves and tenants of dependent lands. Peasants held the dependent holdings, called *manes*, and performed services or paid dues as a form of rent. The peasants and domestic slaves of the manor formed the lord's *familia*. The proportion of *demesne* land on each manor varied from one estate to the next, as did the obligations and standing of the peasants. As a result, the manorial system became the basis of life for most medieval peasants and the economic foundation for the landholding elite.

Despite comprising the majority of the population, very few records concerning peasants survive. By the eleventh or twelfth century the concept of the feudal order had emerged that recognized contemporary society as one divided into "those who fight, those who pray, and those who work." This does not mark the birth of a peasant class, but before this our understanding of the peasant class is nebulous in part because records from the early Middle Ages identify people by their legal status rather than by occupation. They use terms that translate into English as "free," "half-free," and "servile" rather than "farmer" or "laborer." In the early Middle Ages no word existed in either Latin or German that translates as "peasant." "Peasants" appear in the records after the tenth century, when people engaged in agriculture became legally distinguishable from those whose primary occupation was "warrior."

In economic terms, peasants existed as farmers and herders much earlier than they existed as a legal class. Many free peasants populated Europe in the days after the decline of Rome. They inhabited single farms, groups of farms,

and hamlets, but war and natural disaster forced them to move periodically. Moves were not difficult, since they built their dwellings and other buildings from wood, straw, and clay. As agricultural methods intensified and more permanent building materials came into use, the peasants became a settled class. In these uncertain political and economic times, peasants often surrendered their holdings to a local strongman in exchange for protection. The strongman became the manorial lord, and the peasant became part of his *familia*. The lord then granted the land he had acquired back to the peasants. This became the peasant's manse.

Historians believe that originally most peasants were free and that in early Frankish times they served in the king's army in Germanic tradition. As the manorial system spread, powerful landholders emerged, and a military system based on mounted warriors who held fiefs developed. This made military service too far-ranging and too expensive for free peasants to take part. They did not have the wealth to maintain a horse and arms, and they could not be away from their farms on the extended campaigns of the late eighth-century Carolingian kings.

These military developments drove more peasants into manorial servitude. Eventually, two broad groups emerged. The first was manse peasants, who held a house and a piece of land that they worked independently and who owed rents or services to their manorial lord. These peasants most likely descended from freemen. The second group was serfs, who resided on the manor and rendered immeasurable services on demand and for whom the lord was personally responsible. Some historians argue that serfs were not really peasants in the true sense because they were considered chattel, property of the manor to be used as required, be it in the fields, in the workshops, or doing domestic duties. However, from an economic standpoint little differentiates the two groups.

From the outside this system appears homogeneous. From within, however, the system was extremely complex. A peasant's economic and social standing depended on the deal he made with the manorial lord when he submitted. Some peasants submitted only their land and remained free subjects of the king or count, while others

A peasant's work is never done. This illustration from *De Universo* by Rabanus Maurus (1028), shows the back-breaking toil which pervaded the lives of early medieval peasants. Note the figure on the right, bent over an enormous iron hoe. (Bildarchiv Preussischer Kulturbesitz/ Art Resource, NY)

submitted their persons as well as their land and became servile peasants, subjects of the lord. Some agreed to perform services in addition to working on the demesne, some agreed to pay dues in money or in kind, and some agreed to extra labor at certain times of the year. These varying arrangements determined the customs that ruled the relationship between each peasant and his lord, which would also govern the relationship between their descendants. The term "serf" has been used by some historians to distinguish between free and servile peasants and by others to describe all the dependants living on a manor. In reality, peasants classified as serfs had economic arrangements that were as varied and complex as those of free peasants. Peasants of varying social standing with a range of economic agreements often lived side by side with one another on the same manor.

Arrangements that determined social standing of peasants within a village were equally complex. Class identity within lower levels of society appears to have been of little importance. Free peasants were free before the law and could appeal to the king or a nobleman for justice, but economically they depended on their manorial lord, so distinctions between free peasants and serfs quickly became irrelevant. Despite legislation prohibiting marriage between free and

THE PEASANTS' DAY

Ceaseless labor in the home and field marked the daily life of the medieval peasant. Early medieval peasants used primitive wooden implements and tools to till and plant their fields. The peasants' goal was to produce food for subsistence, and agricultural jobs dominated their workload. They were not specialists and performed any job that needed doing. Women also did daily chores around the house and farmyard, made cloth from flax and wool, and assisted in the fields during the planting and harvesting seasons.

In addition to working his own holding, the peasant's duties might include performing services on manorial demesne, performing nonscheduled duties such as mending fences whenever his lord demanded, and performing seasonal duties that might take him away from home for several days as part of a work crew. The duties to the manor took priority over work that the peasant needed to perform on his own holding. If the peasant's wife needed to make flour or bake bread, the lord often required that she use the manor's mill or bakery and pay a usage fee.

There were nevertheless bright spots in the peasant's life. The natural gathering area for peasants was the village church. Often the local market set up in front of the church, and festivals and village celebrations took place there. Medieval peasants celebrated weddings, baptisms, saints' days, and the local church's anniversary. People sang, danced, and drank and held celebrations such as harvest festivals and solstice bonfires that had roots in pagan custom but continued throughout the Middle Ages. On all these occasions, feasts made up for the normally monotonous and frugal meals that peasants ate the rest of the year.

—Kevin Hill

servile people, there appears to have been no hesitation to intermarry. Finally, between the free and nonfree existed a vast number of semi-free people whose situations bore elements of both the freeman and serf.

Aristocrats and Elites in Early Medieval Europe

Aristocratic elites were able to maintain their political and economic authority over much of early medieval European society (300–1000) through their control of landed wealth; however, their position was confronted by the growing importance of towns. Following the decline of the western Roman empire, the Germanic successor kingdoms were unable to create centralized authority due to political and social instability. This situation allowed Germanic warriors to derive certain political and economic rights in exchange for military service. Gallo-Roman patricians were also able to preserve many of the privileges they had enjoyed under the late Roman empire by adapting and marrying into the social structure of their new Germanic overlords. Through their positions as the warrior caste of Europe (“those who fight”) and feudal landowners, medieval elites achieved their level of power by manipulating these positions and playing the Church off against the interests of centralizing European monarchs. From late antiquity to the High Middle Ages, elites consolidated their power through their control of the institutions of the Church, the military, and the emergence of feudalism, thereby ensuring their political, social, and economic domination of Europe.

After the barbarian migrations of the fourth and fifth centuries, Germanic chieftains established political entities reliant on the loyalty of their armed forces on the territories of the western Roman empire. Through the distribution of conquered lands, they secured the loyalty of their subordinates. However, this relationship was reciprocal in that such loyalty was in exchange for these landholdings, allowing the landholder a

level of autonomy within his domains. The Gallo-Roman patricians were able to hold onto their landholdings by utilizing Roman law, which many of the German chieftains abided by to a certain extent, and also by gradually assimilating and intermarrying into the cultural norms of their Germanic overlords. Centuries of cultural contact between Germans and Gallo-Romans, particularly in Italy and Gaul (France), ensured that this was a long evolving process. Intermarriage and common cultural attributes, such as Christianity, created a cohesive social network of both elite Germans and Gallo-Romans in western and southern Europe.

The emergence of feudalism in different parts of Europe took on different characteristics and had differing results for the autonomy of the aristocracy. The social hierarchy of early medieval Europe evolved from that of Germanic warriors given land for loyalty into a form of political autonomy based on service or fealty to the king. The social division of “those who fight, those who pray, and those who work” relegated the elites to positions of the first two but also ensured the subordinate status of the peasants, laborers, and peasants in the latter. Elites inherited their landed wealth and thereby also their responsibility to the king. Aristocratic elites served in military capacities or in high positions in the Church, in essence attaining more land as clerics. From a very young age boys were typically trained to be warriors and were thus imbued with martial values. Elite women were confined to the household, married off to create ties to other noble families, or were sent to serve the Church as nuns at convents, maintaining varying levels of personal agency within such roles. Wealth from their landed possessions allowed them to amass fortunes to spend on castles and luxury goods from the Near East.

The social, political, and economic functions of the elites maintained their importance throughout medieval society. As the warrior caste of Europe, aristocrats fought for the protection of their property and theoretically served their overlord. The fratricidal in-fighting of the early Middle Ages ravaged on in the Frankish and German holdings as those monarchs fought to hold on to their power but also to engage outside incursions by Vikings, Magyars, and Arabs. Throughout this en-

A Merovingian manor house. Built during the Merovingian dynasty (457–751) in Gaul (modern France), the house includes a great court at lower center, surrounded by dwelling rooms and a portico. tire period, the aristocracy also found a place in the institutions of the Church to project their influence and power. As archbishops, bishops, abbots, and other higher clergy, elites were able to control massive expanses of Church lands and political control over the daily lives of the serfs on those lands. As clerics, they skirmished with monarchs and other nobility for political influence. The aristocracy also proved quite influential in the affairs of the Roman Catholic Church, serving as high clergy (bishops, archbishops, abbots). This served to supplement their income as landholders beholden to the Church when they already held lands as fiefs from their secular lord. Noble women were also able to serve in the ranks of the Church as nuns and with rare exception as abbesses. The political fragmentation of Europe into multiple principalities, kingdoms, duchies, etc., increased with the growing power of the aristocracy and its discontent with the English, French, and German kings. Having become major landowners, nobles were exceptionally important to the economy of Europe given that agriculture constituted a significant percentage of the medieval commerce. As the main purchasers of finished goods and metalwork (particularly armor), the nobility ensured the livelihood of townsfolk and city dwellers responsible for manufacturing.

Social relationships between the aristocracy and the bulk of society (“those who work”) were shaped by the reciprocal relationship that existed between them within the structure of feudal society. The economic system of manorialism characterized a local jurisdiction or geographical area owned by a noble. The manor was located near a town or village inhabited by peasants. The lord of the manor was the local ruler of all peasants in his village. He held legal authority over them and was in charge of administering the law through his court. The bulk of the serfs who lived in the manorial properties of the aristocratic lord were expected to work on the lord’s land, fix the roads, pay to use the lord’s mill, and perform other duties expected of them in exchange for protection. In addition, the lord might control a number of serfs, workers who were legally tied to the land. The Peace of God was an agreement made between the nobility and the Catholic Church at the end of the tenth century to protect noncombatants (peasants, townsfolk, lower clergy, etc.) from attacks by soldiers. Town dwellers, merchants, and craftsmen, while having specific rights as freemen when their towns and villages were in possession of royal charters, still deferred to the aristocracy in acknowledgment of their lower social position relative to them. The lower clergy, such as priests, monks, and nuns, also held a subordinate relationship to the nobility, especially to their high-ranking clergy officials of noble background.

Scholar Bureaucrats in Tang China

Scholar bureaucrats formed one of the most powerful social groups within Tang China (618–907). As the group charged with both administering official China and maintaining the cultural tradi-

tions of China, this group held a level of prestige on par with that of the imperial family. Scholar bureaucrats, or *shi*, held their status based on three characteristics: the relative ranking of their clan, their success in the civil examination system, and their role as protectors of Chinese culture (*wenbua*). During the infancy of the Tang dynasty, the aristocratic clans were already positioned as the only group that could lay claim to all three of these characteristics. The status that these clans possessed led to their domination of the upper echelons of the civil bureaucracy.

Young men became officials in several different ways, the two most common of which were the civil examination and the yin privilege. The yin privilege allowed high-ranking officials to place their sons at lower levels of the bureaucracy without having to go through the civil examination. This method of entering the bureaucracy served to perpetuate the power of those families already considered *shi*. The sons of other families, those of lower rank, had to participate in the civil examination system. This highly competitive

Tomb figure of a government official, Tang dynasty. Custom and government regulations decreed that officials be dressed in brightly colored silks and other costly materials. (Museum of East Asian Art)

system tested young men in a variety of subjects and, theoretically, chose the most competent to enter the bureaucracy.

The *shi* were an important part of the Tang government. The duty of the official was to provide advice to the emperor during the decision-making process. The official was expected to challenge the emperor if the official believed that the emperor's decision was not in the best interest of the dynasty. The official could write memos to the court or even withdraw from government as a means of protest. This level of candor between the official and the emperor was part of the prescribed role of the official and ruler within the Confucian governing model. The role of the scholar to stand in opposition to the emperor often caused tension within the court. For this reason, the emperor often acted to undermine the power of the officials.

There were several methods at the emperor's disposal to increase his own power at the expense of the *shi*. Taizong, the second emperor of the dynasty, instituted the nine ranks system. This system was similar to what the Northern Wei (386–534) utilized as a means of sponsoring applicants for government service. The Tang version of this system ranked the clans in order of prestige. Early in the Tang, the northern clans filled the upper ranks of this system. Over time, however, the government successfully included many of the families that rose to prominence through government service to the Tang in the upper ranks. The government also used the civil examination system as a way of controlling domination of the *shi* by the aristocratic families. The civil examination system promoted a meritorious entry into civil service through a test administered by the government rather than through family connection. The role of the government in the exam process fostered loyalty between the scholar and the emperor, as it was the emperor who was ultimately responsible for choosing the final candidates for admission into the bureaucracy. The emperor also utilized less gradual means of limiting the power of the leading clans. Taizong initiated a ban on intermarriage among the great clans in order to dilute the families through marriage with other clans.

The scholar bureaucrat's role as protector of Chinese culture was important as a distinguish-

➤ WEI ZHENG AND TANG TAIZONG

The role of the top officials within the dynasty was often precarious. The top official had a Confucian duty to challenge the emperor when he believed that the emperor was incorrect, but that challenge often resulted in dismissal or execution. Under Tang Taizong, a strong emperor, Wei Zheng often found himself at odds with various plans of the emperor. Wei considered it his duty to mold Taizong into the Confucian ideal of an emperor and encouraged the emperor to remain frugal and to always put the people first in any decision. While Wei advanced within the bureaucracy because of his willingness to challenge the emperor, Wei's position also depended on the emperor's belief that he needed to follow Wei's advice. By 737 Taizong grew tired of Wei's constant criticism and moved him out of the inner circle around the emperor. Thus, the power of the bureaucracy often depended on the willingness of both parties—the official and the emperor—to adhere to their prescribed roles. Failure of one or the other to do so rendered the official inconsequential.

—Robert Williams

ing characteristic of the group. The prestige of the great clans was based in part on their ability to cultivate literary virtues, such as poetry and study of the Five Classics. Other elites extolled families that conducted themselves according to ancient ritual (*li*) and engaged in the study of cultural traditions (*wenxue*). While the great clans claimed a monopoly on these virtues during the early Tang, as the diversity of the official class increased during the course of the dynasty, more families claimed *shi* status.

The scholar bureaucrat claimed elite status in China based on familial or cultural grounds. During the almost 300 years of Tang rule, the control of this class within Chinese society of a relatively few clans from the north of China decreased markedly. During the infancy of the dynasty, the Tang had two goals: to bring the northern clans into the dynasty in order to prevent any move on their part toward independence and to integrate these powerful clans into a government-sponsored system that ultimately favored greater diversity among the officials and

increased loyalty to the emperor. The Tang was largely successful in both of these regards.

Court Society in Heian Japan

The Heian period in Japan (794–1185 CE) began with the capital moving to Kyoto (Heian-kyō) and was the last Classical Period. During this time the Fujiwara became powerful, first intermarrying with and later controlling the imperial family. As centralized and imperial government

declined during this period, the family structure was affected as well.

During the Heian period, aristocratic marriages were usually conducted as visiting marriages. An elite woman typically remained in her parents' house, where her husband would come to visit periodically. These women were expected to stay behind closed doors at all times, even going so far as to stay behind a screen while at home, needing to hide themselves from all males who were not their husbands. This is one of the reasons for the prominence of women in Japanese literature of the time. While some resorted to staring off into space or spending copious amounts of time selecting colors and patterns for kimonos, still others spent their time writing in diaries. This was strengthened by the fact that written Japanese was known as a feminine script, while the court (and therefore male) language was Chinese.

These marital arrangements had both advantages and disadvantages. Outwardly, the women had unstable positions in the marriage because the husband could stop visiting whenever he chose. At the same time, they also had strong po-

► PROTOCOL AND SUPERSTITION—THE LAST TESTAMENT OF FUJIWARA NO MOROSUKE

Fujiwara no Morosuke (908–960) was an important member of the Fujiwara clan who was named *udajin* (“minister of the right hand”) to Emperor Suzaku (923–952 CE) in 947 and married his daughters to Emperor Murakami (946–967 CE), making him grandfather to two emperors. In his will, Fujiwara left instructions to his heirs on how they should live their daily lives. This is a good insight into how structured and ceremonial the aristocrats lived their lives in medieval Japan. It is also an indication of how intensely superstitious they were. Below is an excerpt from his will:

“When you arise in the morning, chant seven times the name of the star for the year. Next look at yourself in a mirror. Next consult the calendar to know the fortune for the day. Next use your toothpick and face west to wash your hands. Next chant the name of the Buddha. . . . Next cut your finger and toenails (cut your fingernails on the day of the ox and toenails on the day of the tiger).

Then select a day to bathe (once every five days). You must consult the fortune before bathing. (It is said in the Biography of the Yellow Emperor that bathing on the first day of the month results in a shortened life. Bathing on the eighth day brings about longevity. Bathing on the eleventh day helps your eyesight, and bathing on the eighteenth day causes suffering from bandits. Bathing on the day of the horse results in the loss of love and respect and bathing on the day of the boar results in shame. Do not bathe on bad days. The bad days are, the days of the tiger, dragon, horse and dog, and the day the star of the long-nosed goblin comes to earth to the food of the human beings.”

—Monique Vallance

Source

Kujodōno Ikai (Last Testament of Lord Kujō), as quoted in David John Lu, *Japan: A Documentary History* (New York: Sharpe, 1997), 73–74.

sitions because any maltreatment or neglect by the husband could result in the wife barring her husband from the household. And because they were living with their parents and not their husbands, they were not dependent on their husbands for money or protection, which meant that husbands who wanted to keep their wives had to maintain a certain level of behavior.

In addition, the marriage politics at the time made having girls more desirable than boys, as it was easier to use them to improve one's social status. The Fujiwaras had married their daughters with the sons of the imperial family. As they grew in importance, their daughters eventually began giving birth to future emperors. While women did not have overt voices in politics, instances such as these gave them indirect control. These visiting marriages meant that young boys lived primarily with their mothers and maternal grandparents and only saw their fathers occasionally. This resulted in mothers having considerable influence over their sons and is the reason that the Fujiwaras were able to gain nominal control over the imperial government.

Despite the control that the Fujiwaras had over the emperors, the respect for the emperor was so great that they never actively sought to overthrow the emperor but instead were content to rule from behind the scenes. Because of this, court culture remained very important. Decorum, appearance, and status were the most important things for a courtier to possess. Status was strictly adhered to, and the showy display of luxury and riches were the norm. In fact, the elites looked upon the commoners as brutish and grotesque. Composure was expected at all times. Any outburst of strong emotion, such as laughing with one's mouth wide open, was looked upon as something to be shameful of. Appearance was something that all were highly conscious of. They were constantly aware of what others thought of them, and this awareness affected their behavior. They were also highly conscious of fashion and clothes; even the slightest mismatch of colors in one's kimono was frowned upon.

Elites during the Heian period spent most of their lives concerned with display and their outward behavior, something they were forced to control even in the privacy of their own homes

and marriages. Due to the women writers who both wrote in their diaries and wrote novels such as *The Tale of Genji*, scholars have an intimate look into everyday life in twelfth-century Japan.

Structure of Korean Society

Korean society up to modern times has been notable for its strongly aristocratic character, a phenomenon that finds its origins in ancient times. The Korean Three Kingdoms of Koguryo, Paekche, and Silla emerged from age-old clan societies, where the ruling chief had wielded power only as *primus inter pares* ("first among equals"). Although powerful kings did eventually emerge from among such chiefs, Korean society throughout the Three Kingdoms and Unified Silla periods and, to a lesser extent, the Koryo period continued to be characterized by a strict social hierarchy that included an aristocracy of birth or mixed birth followed by commoners (to include farmers and artisans) and slaves with little social mobility between the classes.

By the year 300 the Three Kingdoms of Koguryo, Paekche, and Silla had emerged as adversaries for control of the Korean peninsula. Yet despite their mutual rivalry the Three Kingdoms had much in common in terms of social structure. They all possessed clear aristocracies whose members owed their position and privileges to birth. Although few details are known of Koguryo social structure, it is clear from Chinese histories that the higher echelons of Koguryo society consisted of clans whose power was directly related to their proximity to the monarch and their supply of royal consorts. Likewise, we know that eight prominent families comprised the noble class in Paekche, which monopolized its administrative bureaucracy and court.

However, Silla provides the clearest evidence of a centralized monarchy ruling within

Wall painting shows a noblewoman with her serving maids, from the tomb of Dong Shou, Anak, Korea, fourth century, Three Kingdoms period, Koguryo. (Werner Forman/Corbis)

the larger context of a rigid aristocratic society. A strong centralized monarch emerged relatively late in Silla compared to its neighbors. But by about 500 the Silla king had solidified his authority, thanks in good part to the national struggle against Koguryo and Paekche, which demanded strong centralized leadership. The emergence of centralized monarchies in all the Three Kingdoms undoubtedly required concessions between the monarch and the aristocracy, but this was most evident in Silla. In the sixth century the king increased his authority to rule but in the process was compelled to institutionalize the privileges of the aristocratic class. The strict Bone Rank System of Silla was formally institutionalized in the sixth century, reserving the highest offices in the land for the *chingol* (“true bone”) aristocracy and limiting the rise of those of mixed noble-commoner birth to a middle rank of Head Rank Six.

Nevertheless, social mobility was not entirely stagnant in the Three Kingdoms. During the tumultuous period of warfare leading up to Silla unification in 668, merit in battle could elevate one’s social status. Such seems to be the case with the Koguryo figure Ondal. According to legend, Ondal rose from commoner status to high rank due to his valor in campaigns against Paekche. The life of a Buddhist monk also offered more prominent social status or could at

least provide an escape from the rigid confines of Silla society. Many of the Head Rank Six class, no doubt frustrated or disillusioned by the limitations placed upon them, chose to follow a Buddhist path.

As in most traditional settled societies, that of Korea was based on agriculture and animal husbandry. In Silla this included the raising of horses and cattle, the growing of crops such as rice and millet, and the cultivation of silkworms. Particularly with the influence of Confucianism in the Silla period, lip service was paid to the farmers for their vital role in sustaining the life of the nation. In reality, as with most traditional societies, the life of the farmer was one of hardship, which alongside farm labor could include corvée duties. However, the monarch was often perceived as responsible for lessening the sufferings of the peasantry, which included providing relief in times of flood or famine. There were even some cases where kings in Unified Silla distributed land to able-bodied peasants, but the exact nature of such distribution and its motives are not known.

Something analogous to slavery was also a salient characteristic of Korean society from the Three Kingdoms through the Koryo periods (and indeed up to the nineteenth century). The application of the English word “slavery” to traditional Korean society is problematic. Nevertheless, we know from the historical record that Koguryo, Paekche, Silla, and Koryo societies had slaves (in Koryo referred to as *ch’ŏnmin*, or “lowborn”), although their exact status is not fully understood. Fragments of an eighth-century Silla census reveal that in a group of four villages numbering 442 inhabitants, about 5 percent were slaves. From this evidence as well as the historical record, we can infer that slavery never played a major economic role in traditional Korea. Slaves were probably used primarily as domestic servants or to fill jobs traditionally shunned, such as butcher. Nevertheless, their status was hereditary, and manumission seems to have been quite rare and even punishable.

Silla’s defeat of its rivals ushered in the Unified Silla period (668–927) but did little to alter the social order. In the interests of a smooth assimilation, the noble classes of Paekche and Koguryo were largely absorbed into Silla’s own aristocratic caste or at minimum were allowed

to retain their landed estates. For instance, the Silla king granted Ansuŏng (?–683), the self-proclaimed last king of Koguryo, an aristocratic title and clan name and brought him to reside in the Silla capital.

For a brief century or so following unification the Silla monarchy made a determined effort to solidify its authority and break the power of the Silla aristocracy. The Silla kings reformed the administrative apparatus along Chinese lines and attempted to wrest decision-making ability from the Hwabaek Council dominated by the nobility. They even made bold attempts to break the landed source of aristocratic power by divesting aristocratic officialdom of their so-called stipend villages, or large land grants whose production the nobility could exploit in lieu of any official salary. In their place the king instituted a system of regular salaries dispersed by the central treasury. Meanwhile, the lesser Head Rank Six officials supported the monarchy's attempt to stymie the entrenched interests of the noble class.

In the struggle between king and aristocracy that became a salient characteristic of late Unified Silla, the Head Rank Six class was a key component of royal power. They often received royal support to study in Tang China, returning to Silla to staff the increasingly Chinese-style bureaucracy as a counterbalance to the aristocratic officials. Such key Head Rank Six figures as Ch'oe Ch'i-wŏn (857–?) espoused the adoption of a merit-based system for office seekers.

Ultimately, royal attempts to curb the power of the major noble clans failed. The assassination of King Heygong in 780 marked the emergence of a period of extended internecine struggle among the Silla aristocracy during which the power of the throne was largely eclipsed and the centralized government itself broke down. This breakdown of the traditional social order can be seen in an edict issued by Silla's King Hungdok in 834 reminding his subjects that "there are superior and inferior people, and humble persons, in regard to social status." Lamenting a degeneration in social ranks, Hungdok reinstated the old punishments for transgressing the dress and living codes of one's class.

Naturally, the breakdown of effective government resulted in the disintegration of conditions for the peasantry. Thus, the history of late

➤ BONE RANK SYSTEM

The rigid aristocratic hierarchy of Silla society was most evident in its Bone Rank System (*kolp'um chedo*), which stratified Silla society according to bloodline. Originally an informal system, it was codified during the reign of King Chinhung (540–576). Silla society was formally divided into those of hallowed bone (*songgol*) origins, true bone (*chingol*) origins, mixed noble-common origins, and commoners. At first only those of hallowed bone status could assume the Silla throne, while the *chingol* class could attain the highest ranks and government posts. After 654 the *sŏ nggol* class disappeared with the crowning of the *chingol* King Muryŏ I. The Bone Rank System also dictated the color of one's clothes, the size of one's home, and even the types of utensils one could use. Eventually such aristocratic privileges undermined royal authority. Moreover, the system frustrated the ambitions of talented Head Rank Six men of mixed noble-common status. Many Head Rank Six officials transferred their loyalties to the state of Koryŏ, where they were to play influential roles.

—Daniel C. Kane

Unified Silla was marked by increasing social unrest in the countryside. By the ninth century alternate power centers were arising in the provinces, led by men having little or no connection to the traditional elites of Silla. Such figures as Chang Pogo (787–846) and Wang Kon (877–943) emerged from humble backgrounds to positions of great power in the Korean hinterland. It was Wang Kon, a figure linked to maritime trade in northwest Korea, who emerged in the chaos of the final years of Silla to establish the Koryo dynasty in 918, which he would rule as its first king under the name T'aejo.

The last Silla king submitted to Koryo in 927. In one sense the triumph of T'aejo was the final blow to the old aristocratic order of Silla. In early Koryo positions of authority were dominated by a new elite: powerful gentry who had supported T'aejo's rise to power as well as former Head Rank Six officials of Silla. Learning the lessons of Silla's fall, early Koryo monarchs were keen to keep power centralized and society orderly. One's family origins largely determined

one's life pursuit, with military, civil, agricultural, and artisan roles largely hereditary. Although Koryŏ soon set out to establish a more Confucian bureaucratic system based on merit, in reality those of the lower classes had little chance of sitting for the national examinations. The elites had changed, but Koryŏ society proved in many ways more rigid than the Bone Rank System it had supplanted.

The Development of Caste in India

The social system of classes and castes, *varna* and *jati*, constitutes the most prominent and comprehensive social structure in ancient India. Taken together, these two categories are often referred to as caste, a broad term referring to social class that obscures the complexity of the Indian social system. The term *jati* refers to the specific socioeconomic roles of members of a community such as scribes, washers, tailors, weavers, etc. A single community, such as a village, would have had several interdependent *jati*

working together to fulfill all the economic needs of the community. Moreover, *jati* are endogamous, which means that members of a *jati* tend to intermarry within their own group and pass their socioeconomic roles down to their descendants. On the whole, different *jati* may conform or correlate to one *varna* or another.

The term *varna*, then, refers to the religiously sanctioned stratification of society into four broad classes. These four are the *brāhmins*, specialists in the Vedic texts and rituals; the *kṣatriya*, the warriors and nobility who constitute a political class; the *vaiśyas*, the merchants and artisans; and the *śūdras*, the class that serves and performs menial tasks. These *varna* are ranked in terms of ritual purity, with the *brāhmins* being the most pure in religious terms and the *śūdras* the least pure. As this social system expanded from northern India throughout the rest of the peninsula in the latter half of the first millennium CE, the categories of *varna* and *jati* functioned as a means of classifying and assimilating new roles and occupations into a Sanskrit social structure.

Closely related to *jati* were commercial guilds (*śrenī*). Often found in urban settings, guilds were mercantile associations related by similar economic professions and interests. For example, the early centuries of the first millennium CE saw the rise of guilds of silk weavers in western India. What distinguishes a guild from a *jati* is that while the former refers merely to groups with the same or similar economic occupations, the latter term encompasses not only economic but also social and religious roles within a community. The role of guilds as professional organizations also provides some insight as to the possibility of social mobility upward (or downward, as the case may be). For example, by the fifth century CE many of the aforementioned silk-weaving guilds had migrated farther inland into central India and abandoned their profession in favor of more profitable and higher-class occupations as soldiers, archers, and bards.

There is evidence that in earlier periods of Indian history there was more acceptance of movement between classes, but law texts (*dharmaśāstra*) from this period indicate the prevalent perception that caste was fixed at birth, and a person was to remain in that class until death.

➤ GENDER ROLES AND CASTE

Generally speaking, patriarchal social mores prevailed in the caste system of southern Asia. Although the ideal marriage was within a caste group, some dharma texts allowed for hypergamous marriages, in which the husband was of slightly higher caste than the wife. Furthermore, expectations on high-caste women were more stringent. High-caste women were expected to be married before adulthood; sometimes girls were married before puberty. Society frowned on the remarriage of widows. Among *kshatriya* women, the practice of *sati*, in which a widow immolates herself on her husband's funeral pyre, emerged in this period, as attested by an inscription from Eran in

western India dating to 510 CE. A woman's property rights were limited, although customs and laws governing women's inheritance varied by region. In some places, customs of matrilineal descent and cross-cousin marriage were practiced to keep property within a family. For example, Uchchakalpa, in central India, maintained these patterns in this period as a social custom that existed before the caste system emerged in this region.

Ways for women to opt out of a householding life were generally limited. Some became courtesans or joined performing troupes. Others renounced society altogether to join religious orders.
—Matthew Bingley

Nevertheless, as this last example shows, class and caste are not as rigidly defined as they are often portrayed. The process by which a group elevates its social class has been dubbed *sanskritization* and involves inculcating and exhibiting the norms and cultural mores of higher classes, as represented in the Sanskrit literary and religious traditions. For example, by the end of the first millennium, many wealthy landowners, the recipients of land grants for agricultural production and revenue, sought recognition as members of the *kshatriya* class, resulting in an expansion of this class in northern India. Adding to the expansion of the *kshatriya* class late in this period were other groups claiming this status. Administrative scribes (*kayasthas*) claimed status as *kshatriya* as well as a trading class, called *khatri*, who justified their elevated status by claiming a story of their origins as *kshatriyas* who had fallen in status.

Groups beyond or below hierarchies of caste, such as untouchables, outsiders, and slaves (*dasa*), grew more numerous in this period. Untouchability generally referred to those individuals below even the *shudras* in status and whose touch was innately polluting. Untouchables in urban settings were often those who scavenged for a living or who worked in cremation grounds, while those in rural settings were often equated with menial labor. For example, the term *chandala* referred to a caste spe-

Detail of a palace scene showing various castes and ethnic groups, Gupta dynasty (320–600 CE). In theory, broad caste divisions (*varna*) were associated with color, with the lower-ranking *varna* being darker. (SEF/Art Resource, NY)

cializing in the transport and cremation of corpses, the *nishada* referred to rural hunters, and *karavara* was a leather worker. An outsider (*mlechchha*, often translated as “barbarian”) was one whose language and customs differed

and who likewise could not be part of caste society. Outsider groups included tribal peoples, whose customs were alien to South Asian caste society. While some tribal groups were considered untouchable, as they became integrated into caste society tribal chiefs were identified as *kshatriyas*. Finally, increased mention of slavery in the literature of this period indicates an expansion in the institution. Forced labor was prevalent in agricultural and domestic settings, although slaves from untouchable castes did not serve in domestic roles.

In contrast to the caste structure that placed *brahmans* at the top of the hierarchy, religious institutions such as Buddhism and Jainism advocated the abandonment of caste. Moreover, the category of the religious renunciate remained the primary means of leaving caste society behind. Generally, the initiatory rites of renunciation and joining religious orders were viewed as a way of becoming dead to society.

Free People of Early Medieval Islamic Cities

In many ways, the Islamic conquest led to a revival of urban life in the Near East during late antiquity. Cities had been on decline and had become centers for the agricultural communities that surrounded them. City life was dominated by free people who were local landowners. With Islam, cities came to be dominated by merchants, and urban life revived. Free people of early medieval Islamic cities were not all that different from the free people of pre-Islamic late antiquity cities. The Muslim conquests accelerated the change of the urban landscape that had begun long before in late antiquity. The Muslim conquerors took over established cities, and life was not dramatically changed for most people. Even such features as bazaars predated the Mus-

lim conquests. They had been and remained meeting and business places for free people. For some time in the Levantine region, urban civic and public life had been in decline, while private and domestic life became more important. Cities remained centers of commerce, and many free people were artisans, craftsmen, or traders. Gradually, the late antiquity cities and their inhabitants were transformed, but many cities and their populations retained elements from their Hellenistic and Persian foundations.

Most of the cities of this period were ancient urban centers whose histories long preceded the Muslim conquest. Jerusalem, Aleppo, Damascus, Alexandria, and Antioch are just a few. Still, the Muslims founded new cities such as Kufa and Basra in Iraq, Fustat in Egypt, and Qayrawan in North Africa. In addition, there were the Muslim cities of the Hijaz, where Mecca and Medina remained preeminent. Still, life in these cities would not have been dramatically different for the average free person just because of the advent of Islamic rule. However, some of these cities, such as Kufa and Basra among others, were founded as garrison cities for Islamic soldiers. In the later Umayyad period (684–750) these cities underwent a transformation as many peasants moved in from the countryside and converted to Islam. Also, many slaves converted to Islam, a move that often brought freedom so that they were able to join the ranks of free people in the cities. By the end of the early medieval period, the distinction between ruler and ruled among the populations of Islamic cities was not so great, as more and more free people converted to Islam, Arabicized, and demanded a greater role in religious and political life.

Muslim leaders continued to found cities. Al-Qahira, Cairo, was founded by the Fatimids in 969, and Fez was founded in 788–789 by Idris Ibn Abd Alla. Baghdad was founded as the new Abbasid capital in 762. These cities, like the others, became cosmopolitan cities with free people from diverse backgrounds.

Many of the free people in Islamic cities were relatively prosperous. Some were landlords connected to the countryside, while others traded in agricultural products. Some were artisans, including metalworkers, goldsmiths and silver-smiths, carpenters, papermakers, bookbinders,

scribes, calligraphers, butchers, bakers, and leatherworkers. Eventually, many of these artisans would become organized in guilds, although the nature of Muslim medieval labor organization is the subject of some debate. Tradesmen were headed by an *amin*, who regulated the trade organization and wielded considerable power, but the guilds were still not as powerful as their European counterparts.

Some Islamic cities, such as Damascus and later Baghdad, became great manufacturing centers for luxury goods. Some of the wealthiest free people of societies were merchants. Although the early Arab Muslims romanticized their nomadic past, in reality Islam was an urban religion, having arisen in the cities of Mecca and Medina. While these centers were actually just towns, they were still some of the largest settlements in a region of nomads, but some scholars regard them as only protourban settlements. Muhammad himself was a resident of Medina and was a merchant, not a nomad. Thus, the strongest centers of Islam were the urban centers to which free people were drawn by economic and cultural opportunities. These people were not forced to convert, however, and Muslim cities in this period were among the most ethnically and religiously diverse in the world. The free people might be Greek and Arab Christians, Bedouin tribesmen, Chinese, Indian, Jews, and Persians of varying faiths.

Free city dwellers often lived in sun-dried brick houses. Decoration was concentrated on the interior as domestic life rose in importance. Muslim homes looked inward; at the center was a courtyard and fountain, much like an ancient Roman villa. However, in many cities, wealthy merchants built palatial houses and villas. Government officials might vie with merchants for wealth and prestige, but many were not wealthier than other middle-class inhabitants, especially those in smaller towns.

The role of free women in early medieval Muslim cities is less certain. The prophet's wives were models for Muslim women, and they owned property, actively traded, and had a voice in the affairs of the Muslim community. However, the role of women became more secluded in the course of the medieval period, although women in the Muslim world still enjoyed a greater degree of freedom than their Byzantine or West Eu-

ropean counterparts. Muslim women could own property, initiate divorce, and engage in business, and there is ample evidence to suggest that a wealthy and active class of urban women did arise in early medieval Muslim cities.

By the year 1000, the Islamic empire had begun to break up into regional centers. Urban populations remained similar and included merchants, artisans, scholars, and others. However, the different regions developed on divergent paths. Cities in the former Sassanian empire once again were Persian, while cities in North Africa took on local characteristics. Islam was still a unifying factor, and scholars and merchants traveled as free people throughout Muslim cities, but the political and cultural unity that characterized the early medieval Muslim period was no longer in existence.

People of European Towns and Cities

The towns and cities of western Rome late antiquity declined in population and importance between 300 and 550 CE. Although northern towns were the first to lose their administrative and patrician classes, their slaves and long-distance merchants, and their military garrisons and intellectuals, by the early sixth century town life had ceased throughout much of the former western Roman empire. The collapse of the Roman villa system meant that the countryside could no

► TRADE AND DISEASE—EXCERPT FROM HISTORY OF THE FRANKS

Bishop Gregory of Tours, historian and theologian as well as the leading prelate in sixth-century Gaul, noted that trade and concentrations of people often meant the outbreak of epidemic disease, as in sixth-century Marseilles.

“In the meantime a ship from Spain put into port with the usual kind of cargo, unfortunately also bringing with it the source of this infection. Quite a few of the townsfolk purchased objects from the cargo and in less than no time a house in which eight people lived was left completely deserted, all the inhabitants having caught the disease. The infection did not spread through the residential quarter immediately. Some time passed and then, like a cornfield set alight, the entire town was suddenly ablaze with the pestilence. Bishop Theodore came back and took up residence in St. Victor’s church, together with the seven poor folk who remained at his side. . . . At the end of two months the plague burned itself out. The population returned to Marseilles, thinking themselves safe. Then the disease started again and all who had come back died.”

—Joseph P. Byrne

Gregory of Tours, “History of the Franks,” in *Readings in Medieval History*, ed. Patrick Geary (Lewiston, NY: Broadview, 1989), 178.

longer support urban populations. Germanic invaders also aided urban decline since they had little use for the niceties of town life beyond the provision of necessary goods and services. As in most cases administrative duties passed to Germanic warlords and Christian bishops, and the urban fabric and social life disintegrated more or less slowly as local conditions dictated.

By the sixth century the numbers and variety of inhabitants of ill-defined towns had plummeted. Artisans in metal, ceramics, wood, textiles, leather, and perhaps glass found relative safety within surviving or shakily reconstituted Roman walls. They rubbed elbows with the servants of the Church, local lords, and the war-

riors or soldiers who served both. Merchants generally dealt in narrow ranges of local produce and merchandise and were more likely to be itinerant than sedentary. In very general terms towns had an upper class of locally important nobles, clergy, and perhaps old Roman landlords; a middling class of free craftspeople, trades people, and civic functionaries; and a lower class of slaves, serfs, servants, widows, and those needful of charity. The south, however, still contained an array of urban specialists, and port towns that still conducted trade with the Byzantine or Islamic worlds retained the most cosmopolitan populations. Under the Franks town life tended toward stability and growth, but these towns suffered during the invasions of the ninth and tenth centuries.

Dhimmi and Dhimmitude— Non-Muslims in Muslim States, 632–1000 CE

After the great conquests of the Muslim armies in the seventh century, the caliphate faced the critical issue of ruling over substantial populations of Jews and Christians now under its authority. Classifying their status as *dhimmah* (meaning “protected,” in the sense of their religious rights) and them as *dhimmis*, Muslims recognized a commonality in the nature of the revelations followed by these monotheists. The prototype for this concept stems from the earliest moments of the Islamic movement when the Prophet Muhammad (ca. 570–632) had been asked to arbitrate in a long-standing feud between tribes native to Yathrib, later known as Medina (located roughly 240 miles to the northeast of Mecca).

As part of his agreement to do so, he required all the people of the city to enter into a

series of agreements—known as the Constitution of Medina—that set out the rights and responsibilities for each group within the collective. Included in these agreements were the Jewish groups that formed an integral part of the military and economic strength of Medina. Constituting nearly half of the city's population by some estimates, the Jews of Medina are mentioned explicitly in Articles 25–30 and 46 of the constitution, where they are referred to as an *ummah* (community) among the believers. However, this relationship did not remain cordial. After the Jews failed to accept him as a prophet, Muhammad acted against them. Declaring that the Jews had failed to uphold their duties as mandated by the Constitution, Muhammad was able to liquidate a potentially dangerous internal element.

With the reign of the caliph Umar I (634–644), expansion outside the Arabian Peninsula began in earnest. However, it is important to note that the nature of this expansion—and by extension the growth of the Islamic polity—was crucial in how the native populations were treated. If the conquest of a territory occurred under the force of arms, it was designated as *ard al-unwab* (land of force or violence). Lands conquered in this way were under the direct administration of the state after they were forcibly pacified. Agricultural lands were appropriated, and tax levels were set by the regional governor. However, if a territory capitulated without contest, it qualified for the legal status of *ard al-sulh* (land of treaty). In both cases monotheists were allowed to practice their religion, but religious communities could negotiate for favorable terms in territories that were *ard al-sulh*.

Generally, there were two taxes that were levied on territories conquered or acceding to Muslim rule. The *kharaj* (land tax) was assessed on land seized by force. Most important for our discussion, though, is the *jizya* (capitation tax, or head tax). This capitation tax was applied to all inhabitants who did not convert to Islam (i.e., *dhimmis*). Thus, in exchange for the payment of this tax, which signified the *dhimmi's* formal acceptance of Muslim hegemony, individuals and religious communities were allowed a measure of freedom in conducting their business, personal, and spiritual affairs. In this way, many

➤ THE PACT OF UMAR I

The *Pact of Umar I*, while now largely considered to be formulated much later than the reign of the second Rashidun caliph, is nevertheless a critical text in understanding the nature of confessional relationships in the Islamic world. While we have different forms of this document preserved (each worded slightly different), there are some points common to all extant versions.

Included in the covenant were injunctions prohibiting the building of new monasteries, convents, and churches. Likewise, the repairing of dilapidated religious buildings or ones located in Muslim sections became forbidden. Security matters were of grave concern, and therefore the harboring of foreign spies invalidated the freedoms and rights of the *dhimmi*. It also became important to visually distinguish between Muslim and non-Muslim, so sumptuary clauses were included. These included the calling for distinctively colored headwear, footwear, and devices that were worn on the outside of clothing to denote one's religious affiliation. As part of their agreement the *dhimmi* were exempt from military service, but that meant that they could not arm themselves under Muslim law. The paramount role of Islam in society was to be respected at all times. Thus, religious activities had to be conducted in an unobtrusive manner, quietly and away from the Muslim public. Also honored were Muslim dietary laws, as it was expressly forbidden to tempt Muslims with pork or alcohol (although private consumption by the *dhimmi* was allowed). Finally, while it was illegal to preach to the Muslim population, any *dhimmi* who decided to convert to Islam was allowed to leave. Thus, while Islamization was a slow process after the conquest period, it was a provision in the covenant.

—Rasheed Hosein

dhimmis rose to prestigious and exalted posts in both the government and the economy. Often, especially in Islam's early days, *dhimmis* formed the backbone of the bureaucracy, reprising their former jobs for their new rulers. Opportunities for advancement were also available, and there are records of *dhimmis* serving in almost every political post, including that of vizier (the highest civil office).

Injunctions for this accommodation can be traced directly back to the Quran and its assertion: “Let there be no compulsion in religion” (II:256). However, the Quran goes on to note: “Fight those who believe not in Allah, nor the Last Day, nor hold that forbidden which hath been forbidden by Allah and His Messenger, nor acknowledge the religion of Truth, (even if they are) of the People of the Book, until they pay the *jizya* with willing submission, and feel themselves subdued” (IX:29). In this way, the Quran provided a reliable means of dealing with these monotheist groups, given the failure of the Prophet’s attempt to provide them with direct inclusion in the community at Medina. Thus, the status of the *dhimmi* populations of the caliphate was a legal distinction of Quranic origin.

However, while the Quran laid out a basic framework, the injunctions contained within were not comprehensive enough for any practical application. Therefore, Islamic legal scholars drew on another textual source—known as the *Pact of Umar I*—as the exemplar for the rights and responsibilities of the *dhimmi* vis-à-vis their Muslim rulers. Although it is attributed to the caliph Umar I, the pact is now largely believed to be a back projection from jurists of later historical periods seeking to attribute what emerged as customary practice back to the era of the pious Rashidun caliphs (632–661). The overarching theme of the covenant, in its multiple extant iterations, is the safeguarding of the *dhimmis* and their religious sites, provided they pay the capitation tax to the Muslim authority. However, this pact also restricted the public and even private lives of *dhimmis* in ways that underscored their inferiority to the Muslim True Believers.

Social constraints aside, the status of *ahl al-dhimma* (people of protected status) had very far-reaching effects for non-Muslim populations throughout the Islamic world. In many key regions of the caliphate such as Egypt, Syria, and Iraq the dominant Christian creed was not the one recognized by either the Latin Church in Rome or the Orthodox Church in Constantinople. Stemming largely from the aftermath of the Fourth Patriarchal Council at Chalcedon (451), these so-called Oriental churches found themselves on the wrong side of a debate on the nature of the Christ, leading to excommunication,

marginalization, and persecution by the Holy See in Rome and the armies of the Byzantine emperor. When Muslim armies appeared with their offer of security, many communities accepted Islamic hegemony because, for the price of the *jizya*, it offered a measure of religious freedom that was not forthcoming from the previous elite. In this way some churches, such as the Coptic Orthodox Church, the Syriac (or Syrian) Orthodox Church, and the Armenian Apostolic Church, which were threatened with (often brutal) persecution by the Byzantines, were spared and indeed thrived under Muslim rule.

That is not to say that Muslim rule was universally benevolent. There were episodes of repression and even forced conversion in the historical record. However, a careful study of the dating of these events may reveal an alternate rationale. During the reign of the Fatimid caliph al-Hakim bi-Amr Allah (r. 996–1021), the *dhimmi* populations of Egypt and Syria faced brutal repression. Christians were forced to wear large wooden crosses, and both Jews and Christians had to wear black hats to distinguish themselves from the Muslims. In 1007 the caliph also destroyed the Church of the Holy Sepulcher in Jerusalem, one of the holiest sites in Christendom. However, this caliph may have been influenced by millenarianism. A look at the *hijri* calendar—which is the major Islamic calendar that is based on lunar cycles—revealed that the Fatimid caliph ruled from 386 to 411 AH (circa 996 to 1020 CE), with the destruction of the Holy Sepulcher occurring right at the year 400 AH (circa 1009 CE). This is not an isolated phenomenon. Careful study reveals that episodes of *dhimmi* persecution tended to line up with *hijri* centenaries, but this is not a definitive answer to the sporadic persecution of non-Muslims in the caliphate.

In the end, while the caliphate afforded Christian, Jewish, Zoroastrian, and later Hindu *dhimmis* a measure of security and religious freedom that was not generally available elsewhere in the premodern world, the social construct was not utopian. Rather, it was a privilege extended to non-Muslims that evolved from the piecemeal nature of conquest in the early Islamic period and served to normalize tricky relationships between the rulers and the conquered. The true legacy of this institution is its longevity,

serving as a hallmark of Islamic dynasties until the eighteenth-century concept of the state and its importation to the Middle East by colonial powers rendered it anachronistic.

Serfdom in Late Antiquity and the Early Medieval Age

Serfdom was a system by which the elite in agrarian societies appropriated the wealth produced by unfree peasants. Serfdom was a system practiced in many if not most agrarian societies throughout much of history and has an ancient origin. Although the most commonly understood concept of serfdom is of West European origin, institutions very like or identical to West European serfdom prevailed in ancient Mesopotamia, Egypt, China, Greece, and the Roman empire. In classical Greece, the helots were virtual serfs. It is commonly held that one of the antecedents of serfdom in western Europe was the practice in the late Roman empire of settling quasi-free men, or *coloni*, on lands that had, in the early empire, been worked by slaves. Alternatively, slaves were settled on vacant land as *coloni*. Others see the effective origin of West European serfdom in the collapse of the security

provided by the Carolingian empire. This explanation holds that free peasants exchanged their freedom for protection from bandits and other marauders. The feudal bargain, according to this rendition, is that the peasants willingly submitted to a loss of freedom for the security promised by a force of knights and other warriors. A more cynical view is that horse-riding warriors imposed serfdom on defenseless farmers.

Serfdom, like slavery, was a condition of inequality, but societies recognized more rights for the serfs than for the slaves. Usually, serfs were settled on plots of agricultural land that they worked for their own sake as well as for the sake of their masters. In most cases the serfs had recognized rights to the land, including passing the land to their descendants in inheritance, but in all societies they were obliged to pay the master, or lord, for these rights by laboring in the master's fields and/or his household and by paying money or produce, often a large share of his crop. Serfs were required to exhibit marks of inferiority by kneeling or bowing in the lord's presence. Serfs were universally bound to their land and were subject to severe reprisals for abandoning their land and their lord.

Serfdom was most classically defined in Europe and the Mediterranean in the later Roman empire and after its fall, but it was also practiced in various forms in China, India, Persia, Korea, and Japan, indeed in most agrarian societies. Usually, centralized states preferred, for purposes of taxation and military recruitment, a free peasantry without serfdom. China, under the Northern Wei, Sui, and early Tang dynasties, attempted to preserve or create independent landowning peasantries with their Equal Field System. Korea and Yamato, Japan, also tried to institute equal field systems. The Byzantine empire likewise tried to assure itself of an independent peasantry with its Farmers Laws of the seventh and eighth centuries.

However, in China, Korea, and Japan, regardless of the Equal Field System, growing numbers of peasants were forced into serfdom when the governments gave allotted peasants with the land they tilled for the support of Buddhist and Daoist monasteries. In Europe, rulers likewise gave peasants with land to Christian monasteries. In East Asia, as the population grew and as

central governments became unable to enforce the Equal Field System, local elites acquired more and more land, with peasants losing their independence through debts, declining into a condition very like West European serfdom.

Land tenancy and landlordism, in which landlords owned large tracts of land and rented it to peasants to farm, was widespread. This was the most common system in the Islamic lands, most of India, and much of China. Sharecropping, by which the tenant rendered a share, often half or more, of the land's produce to the landlord, was a common arrangement. Tenancy was not the same as serfdom because the tenant was free to leave one landlord for another, but it could and often did evolve into a system of debt peonage, little different than serfdom. In debt peonage, the peasant accumulated a burden of debt to the landlord that was impossible to pay off and that effectually bound him to the landlord.

Serfdom developed early in western Europe but by the sixteenth century had disappeared from large areas. Ironically, the peasants were free tenants in early medieval Kievan Rus. It was not until the mid-sixteenth century that Russian peasants were forced into serfdom by a series of governmental decrees that deprived them of the right to move from the land of one lord to another.

All early medieval societies believed in and practiced social inequality. Serfs occupied the bottom rung of the social order; only a few slaves were considered inferior to them. Indeed, the word “serf” derives from an Old French word meaning “slave.” Another word for “serf” was *villein*, which had the same connotation as the modern word “villain” and meant “ugly, rude, and uncouth.”

Most religions gave positive sanctions to social systems practicing serfdom. In Christian countries, the clergy taught that it was the serf's duty to serve his lord, to give his lord loyalty and love. Other religions taught that the serf's duty was to fulfill his allotted role in this life with the promise of a better life in the next world.

Slave Soldiers in Early Medieval Dar al-Islam, 632–1000 CE

Early medieval Muslim states were unique not only in the extent to which they employed slave soldiers but also in the power and prestige these soldiers attained while still military slaves.

A military slave is definable as a man of slave origin who, after a long training in military service, would have spent most of his life as a professional soldier. Many words have been used to describe slave soldiers. They were at first called *ghulam* (a young servant), and afterward the term *mamluk* (a property) was used for a slave soldier with lighter skin.

Military slavery was almost nonexistent at the beginning of Islam. During the initial campaigns of conquest, in the seventh century, military slaves were members of the Bedouin tribes of the Peninsula. It was not until the beginning of the eighth century that the first slave soldiers emerged.

The Abbasid caliphate was the first to employ large numbers of slave soldiers. During the al-Mansur (754–775 CE) and Harun al-Rashid (786–809 CE) caliphates, a process of military slave requisitioning, from the most peripheral regions of Dar al-Islam, became a normal practice. These slave soldiers demonstrated loyalty to the caliph, who granted them privileges and financial rewards. This step was related to the caliph's regional support; the Abbasid conquest of the caliphate was connected to the Iranian region of Khorasan, where the revolution, which toppled the Umayyad reign in 750 CE, began.

The Iranian phase, which was followed by a Turkish phase, resulted in a rapid increase of military slaves. These became the praetorian guard of the caliph. During the reigns of al-Mamun (813–833 CE) and al-Mutasim (833–842 CE), there were systematic and large-scale increases in slave recruitment for military purposes. The majority of the slaves came from central Asia; the town of Samarqand (in present-day Uzbekistan) was an important slave-trading center where the

nonconverted Turkish soldiers were considered the best option in creating a new army.

Slaves served full-time, receiving regular wages; wore distinctive clothes; and lived in separate headquarters of the towns. In Baghdad, the Abbasid capital, the caliphate palace was surrounded by a military quarter where, in the ninth century, the slave soldiers were in the majority. Al-Mutasim decided in 835 CE to move the capital to Samarra, an Iraqi town 70 miles north of Baghdad, because relations between the military slaves and the civil population had become hostile and violent.

The Mutasim caliphate increased the army of Turkish slaves to 70,000 professional soldiers. These troops were dressed in gold and silk brocade with silver ornaments and other jewels, which provoked jealousy from other army regiments. The Turkish slave soldiers became so powerful that they were able to depose caliphs and raise others to the throne. Turkish slaves murdered Caliph al-Mutawakkil and installed his son, al-Muntasir, as caliph.

By the middle of the ninth century, the armies of most Muslim states consisted largely of slave soldiers. In Muslim Spain and Morocco, Slavic slaves, purchased from Venetian and other West European slave traders, served in the armies. In Egypt, slaves from Nubia and other areas south of the Sahara joined Turks in the ranks. But in most Islamic states, Turkish and Kurdish slaves comprised the bulk of the forces.

As the caliphs came to be weaker and more ineffectual in the late eighth century, the caliph's chief official, the vizier, emerged as the actual commander of the slave troops. The office of vizier came to be hereditary in a few Persian families, eventually being held by the Buyids of southern Persia. The Buyids recruited a new slave force of infantry stiffened by slave cavalry from the Ghaznavid region of Afghanistan. In 1055 CE, the Seljuks, a new Turkish group, defeated the Buyids. After 1000 CE, Muslim Turkish-ruled states continued to recruit slave soldiers until the early nineteenth century.

FAMILIES OF TURKISH SLAVE SOLDIERS

Ibrahim ibn al-Abbas al-Suli is the progenitor of the first Turkish family under the command of the Abbasid dynasty with military and administrative responsibilities. They began to be engaged in the organization of slave armies during the al-Mansur caliphate, and they reached the most important position in command during the al-Mamun reign for the level of devotion shown by his Visir, al-Fadl ibn Sahl, the preeminent caliph adviser.

The Tulunid family, of Turkish background, obtained the *wali* (government) role in Egypt after being a member of the central Asian Turkish guard, initially formed in Baghdad, and later settled in Samarra after its establishment as the seat of the caliphate by al-Mutasim. They became a vassal family of the Abbasid caliphate, establishing an independent Turkish-Egyptian army able to maintain control of Egypt, Palestine, and Syria between 868 and 909 CE. Ibn Tulun organized an army composed of Sudanese and Greek slave-soldiers. His military prowess was strengthened by his multiethnic regiments of black Sudanese soldiers, Greek mercenaries, and fresh Turkish troops from Turkestan. This specific army, in which all the soldiers converted to Islam and were compelled to learn Arabic quickly in order to understand military orders, was the model for the Ottoman slave soldier army of Janissary (new army in Turkish), the elite of the Turkish empire, which emerged during the fourteenth century when religious indoctrination and multiethnics were the main characteristic of the superiority of this army.

Early Medieval Slavery— A Global View

Slavery has existed in human societies at least since people became sedentary 10,000 years before the present. In slavery, the masters are dominant and own the slaves, who are subordinate and have no rights over their persons, property,

or fruits of their labor except as the master allows: slaves are the property of the master. In most societies, slavery was hereditary; a child of a slave was born in slavery and transmitted its slave status to its offspring.

Virtually all agriculturally based societies practiced slavery and serfdom during the early medieval age (300–1000 CE). From Christian Europe to Buddhist Japan, in China and India, in Islamic lands and in Africa south of the Sahara, among the Mesoamericans and the Andean indigenes, among the Icelandic Norsemen and the Polynesian islanders, slavery was a common and universally accepted social status.

Some slaves, almost certainly a minority, were born to slavery, but in most countries, slaves did not produce enough children to replace themselves. It was constantly necessary to recruit new slaves by purchase or capture to keep the institution functioning. One of the most common methods of obtaining slaves was through war. Prisoners of war were commonly sold as slaves, and the purpose of some military campaigns was to obtain slaves. Charlemagne's armies are reputed to have conducted wars against the Slavic tribes to capture slaves. It is no coincidence that the English word "slave" resembles the ethnonym "Slav"; the two words have a common origin. Muslim armies in central Asia are said to have paid their troops in enslaved captives, and thousands of Sogdian and other central Asian oasis dwellers were sent to Chang'an and Luoyang as slaves by the triumphant soldiers of the Tang dynasty. The Viking raids against the West European coastlands were conducted largely to capture slaves; the Norsemen who settled Iceland brought so many Irish slaves to the new settlement that the DNA of modern Icelanders reveals a substantial Celtic biological inheritance. Musa ibn Nusair, the Arab conqueror of Spain, is said to have brought to Damascus in his triumphal train 25,000 enslaved Visigothic maidens.

Slaves were one of the principal commodities traded on the Silk Roads, the trans-Saharan trade routes, and perhaps the Indian Ocean route. They were among the most common items of commerce between civilizations and cultures. China during the Tang dynasty and the Umayyad and Abbasid caliphates, the wealthiest centers of economic activity, were the principal destina-

tions of the slave trade. Scandinavian freebooters regularly brought Slavic captives to the markets of Baghdad and other Muslim cities, while West Europeans sold slaves in Cologne and other Rhenish markets. Many of these slaves were transported down the Rhone to Marseilles, where they were then shipped to Egypt and ports on the eastern Mediterranean. Another well-trodden route for the slave trade was by camel across the Sahara Desert. African slaves were brought north from the West African city of Aoudghost to the Moroccan city Sijilmasa, where the slaves were distributed to cities on the Mediterranean littoral. Egypt obtained African slaves from its southern neighbor, Nubia, and Iraq obtained them via the Indian Ocean trade from the Swahili cities on the East African coast. Slaves were also shipped to India from the East African coast.

The early Tang dynasty imported slaves from Korea, Parhae, the Turkish tribes on the northern frontier, and the oasis cities in central Asia but primarily from the non-Chinese indigenes in the still lightly settled and somewhat wild regions of southern China as well as from Southeast Asia. After An Lushan's rebellion, the Tang dynasty was usually too weak to obtain slaves from the north and west; in fact, during the late Tang dynasty, many Chinese were enslaved by the northern barbarians. However, slaves continued to flow from the southern regions.

Slaves were often used in agriculture and also in most other lines of economic activity. They tilled much of the land in Charlemagne's royal domain and were widely used in Islamic lands, where they were probably partly responsible for the dramatic increase in agricultural production of the Islamic agricultural revolution. Slaves were also used to construct the vastly expanded irrigation systems that were the basis of the Islamic agricultural revolution, and their work likely included digging new wells and deepening old ones and digging underground water channels and surface irrigation canals. In southern Iraq and elsewhere, slave gangs operated vast sugar plantations.

Among the most difficult jobs were those in the mines. Some free labor was used in the silver and salt mines, but often the mine owners preferred to own their labor source. Silver and copper mines in central Asia, China, and Egypt

depended on slave labor, as did gold mines in West Africa and Southeast Asia. Salt mines in the Sahara Desert used enslaved Saharan indigenes. Iron mines throughout the Eastern Hemisphere depended on slave labor, as did many of the smelters and charcoal makers.

Sea transportation, particularly in the Mediterranean, needed numerous galley slaves to man the heavy oars, as did naval vessels. Whenever there were tasks that were extremely difficult, demanding more than ordinary effort, injurious to health and sometimes resulting in early death, tasks that free people would avoid if possible, slaves were used.

Other slaves were entertainers, such as actors and geishas. Some female slaves in wealthy Muslim households were carefully trained as songstresses. Many female slaves were used in the sex trade as prostitutes. Many wealthy households had slave servants who enjoyed an enviable existence when compared with that of agricultural and other slaves and even when compared with many nominally free people cursed by poverty.

Toward the end of this era, slaves were used to man many Muslim armies. These slaves would sometimes rise to very high military ranks. Military slaves, often from Turkish tribes, would become a pampered caste and a danger to civil society.

A question arises: Was slavery necessary for agricultural societies? Could many of the difficult tasks, in which the laborer was called upon to sacrifice his well-being and even life, have been accomplished? The jury is still out on that question.

Zanj Slave Rebellion in Southern Iraq

In the early medieval age, slaves were used in nearly every Eurasian society, and occasionally slaves rose up in massive rebellions. This nor-

mally happened only when large numbers of slaves were employed in brutalized working conditions. These conditions prevailed in southern Iraq in the ninth century.

Late ninth-century southern Iraq experienced an agricultural boom. A growing demand for cotton and sugar, stimulated by the expanding textile handicraft industry and consequent larger urban population of Baghdad and its environs, resulted in an acute demand for land that could be irrigated and made productive.

Wealthy Basra landowners reclaimed land by draining the salt swamps southeast of the city. To be made productive, this land required a heavy investment in labor. The burgeoning trade between Baghdad and the East African coast supplied African slaves to meet the demand for labor. Some sources report that up to half a million black slaves were imported in the ninth century. These slaves not only drained the swamps and removed the salt-impregnated top layer of soil but also worked the cotton and sugar plantations that were established on the newly opened ground.

These Africans, known as Zanj, worked in large gangs. Some labor gangs numbered 500 or more men. Working in deplorable conditions and fed very poorly, the Zanj were receptive to the call to rebel made by Ali ibn Mohammed in September 869. Ali ibn Mohammed claimed to be a descendant of the Prophet Mohammed, but he became a Kharijite, claiming that any pious Muslim, even a black slave, was qualified to be elected to the caliphate.

The Zanj Rebellion spread until it liberated most of southern Iraq and some of neighboring Iran. The Zanj built a capital named al-Mukharah on the salt flats and fielded armies that defeated the forces that Caliph al-Mutamid sent against them. Zanj forces were supplemented by numerous black troops who deserted from the caliph's army.

Some of the disaffected Shia peasants of southern Iraq also joined Zanj forces. In 871 the Zanj Army sacked Basra and later even threatened Baghdad itself. The rebels cut commerce between Baghdad and the Persian Gulf, threatening the prosperity of the caliphate.

Through the 870s, the Zanj state was independent and undefeated. The caliph's most trusted general was his brother, al-Muwaffaq,

whose forces suffered defeat after defeat at the hands of the Zanj. But in 879 its armies stiffened with new levies of Turkish slave troops, and assisted by forces sent from Egypt, the caliphate made a concerted effort to crush the Zanj Rebellion. Al-Muwaffaq, still in command, made slow progress; the Zanj stoutly defended their independence and required four years before their revolt was defeated. Step by step, al-Muwaffaq's forces pushed the Zanj back. In 881 he laid siege to the Zanj capital, building a permanent camp from which to attack al-Mukharrah. Finally, in August 883, the Zanj defenses were breached, and al-Muwaffaq's troops snuffed out the rebellion. The victorious army presented the caliph in Baghdad with Ali ibn Mohammed's head on a pike.

Serfdom in European, Islamic, and Chinese Societies

Serfdom was practiced concurrently in medieval societies as diverse as western Europe, the Islamic Middle East, and China. Serfs in these societies were forced laborers who were bound to the land and belonged to the lowest social classes. Serfdom was not simply an economic relationship but also provided a stable political relationship in systems of social inequality. Serfs were usually considered the property of the landlord, but not in the same way that slaves were property. Serfs differed from slaves in that they were allowed to own property and could not be sold apart from the land on which they worked. Although serfs owed their labor to the landowners, they were also usually given legal and physical protection as well as the right to use lands and common facilities provided by their lords. Although there were some differences in how serfdom worked in European, Islamic, and Chinese societies, the general framework of the serf system was very similar in each society and was central to their economic and social structures.

Scholars long believed that European serfdom emerged in the framework of what historians have traditionally termed feudalism, a hierarchical system of legal and military obligations that members of the nobility had with one another and that served as the basis for organizing medieval society. Serfs fit into this organization because they were usually tied to the lands they lived on and worked on behalf of a noble, who in turn had been granted the right to administer that land by a higher-ranking noble. It is believed that such relationships originated from older practices in the western Roman empire. The custom of patronage among the Romans, for example, was based on a system in which a stronger patron provided various types of protection to a weaker client in exchange for political and other types of support. Additionally, the reforms of later emperors made some jobs hereditary, most notably farming. With the decline of the Roman government's authority in the West, peasant farmers were forced to increasingly rely upon the local landowner for both physical protection and limited support in tough economic times. Correspondingly, landowners depended on the peasant farmers for the majority of their labor. Landowners at the time also depended on slaves, who should not be confused with serfs because the institution of slavery had much older origins and existed independently of the institution of serfdom.

Although modern scholars have rejected the notion that the broad application of the term “feudalism” to the diverse societies and economic systems of medieval Europe has any real value, the notion of serfdom as a major socioeconomic system in the Middle Ages remains unscathed. Medieval serfs typically lived in crude and simple houses on the lord's manor. They were either granted or leased a small plot of land and assigned a small share of the fields to work. Sometimes they were given farm animals and were usually granted access to the wells, ovens, and other utilities made available for collective use on the manor. In addition to the required labor performed for the lord, the serf was also required to give part of his own crop from those lands he worked for himself as payment for his rent. Other financial obligations (various fees and taxes) were usually paid in the form of sea-

sonal labor that consisted primarily, although not exclusively, of harvesting crops. In serf systems where lords and labors lived up to their responsibilities, there was no moral condemnation of the practice. The Christian Church, for example, condoned serfdom, and Christian monasteries had the most extensive holdings of serfs in medieval Europe.

In the Byzantine empire, the Farmers Laws (seventh–twelfth centuries) attempted to protect the free peasantry, but within time powerful land magnates were able to reduce many peasants to serfdom.

Islamic societies, whether based around the Mediterranean or in the Middle East, adopted and maintained varying forms of serfdom that were equally important to the social structures and the functioning of some of their economies, as they were in western Europe. Although Islam arose out of a nomadic environment where trade dominated the local economy, it spread rapidly as a result of the Arab conquests that took place from the early seventh century to the middle of the eighth century. This expansion led to the creation of Islamic societies extending from the Hindu Kush to the Atlantic coast of modern Portugal. Consequently, a variety of governmental and economic systems were necessary to meet the needs of diverse Islamic societies.

Usually a civil or military officer ruled or administered a village or town on behalf of a conquering Muslim sovereign. This centralization made it tough for serfdom to develop in places where it had not existed before but was ideal for collecting taxes in conquered villages or towns that were based around serf-type systems already in place before their conquest. Lands on which multiple serfs paid various fees and taxes directly to the lord made tax collection much easier, as the administrator could collect directly from the lord rather than from each individual peasant. As a result, it was not uncommon for Muslim rulers to leave serf-type systems in place for administrative reasons after a conquest. The Mamluks, for example, allowed the feudal-type economic system of the Druze and other remote groups of Syrians to continue unabated but with a local administrator keeping a watchful eye. Hence, the rise and expansion of Islam in the seventh and eighth centuries led to the introduc-

LIBERATION FROM SERFDOM

During the thirteenth century as European economies began to become more dependent on money rather than trade in kind or labor, serfdom began to decline in favor of various other arrangements. The text that follows is a document of manumission of a serf granted in 1278 by the Abbot of Peterborough.

“To all the faithful of Christ to whom the present writing shall come, Richard by the divine permission abbot of Peterborough and the Convent of the same place, eternal greeting in the Lord. Let all know that we have manumitted and liberated from all yoke of servitude William, the son of Richard of Wythington whom previously we have held as our born bondman, with his whole progeny and all his chattels, so that neither we nor our successors shall be able to require or exact any right or claim in the said William, his progeny, or his chattel. But the same William with his whole progeny and all his chattels will remain free and quit and without disturbance, exaction, or any claim on the part of us or our successors by reason of any servitude, forever. . . . Given at Borough for the love of lord Robert of good memory, once abbot, our predecessor and maternal uncle of the said William, and at the instance of the good man brother Hugh of Mutton, relative of the said abbot Robert; A.D. 1278, on the eve of Pentecost.”

tion and preservation of serfdom in many Islamic societies throughout the Middle Ages.

In the Far East there is clear evidence that medieval societies in China also practiced a form of serfdom similar to that practiced in West European and Islamic societies. Chinese society was essentially divided between landed elites and an enormous agricultural class consisting of serfs, slaves, and free peasants. Legally Chinese serfs were free, but in reality they could be bonded to a landlord. Like serfs in the European or Islamic societies, Chinese serfs relied on a landlord for

This early medieval woodcut shows serfs plowing, illustrating the serfs' function in the medieval world: to do the manual labor essential for the sustenance of the whole society. (Ancient Art & Architecture Collection/Topham/The Image Works)

their homes, oxen to plow, various farm implements, and even fertilizer. Unlike European and Islamic societies, there were no contractual relations between Chinese landlords and serfs.

The institution of serfdom was carefully monitored by Chinese authorities, who sometimes attempted to limit its expansion because of the state's interest in taxing and exacting military service from the free peasantry. During the Northern Wei dynasty (ca. 439–534), for example, officials sought to limit the power of lords who controlled lots of land and serfs through the implementation of an equal field system of land tenure, which they believed would increase tax revenues. The Tang dynasty (ca. 618–907) also periodically used the equal field system to redistribute land to free peasants, who were then subject to taxation and military conscription.

The equal field system broke down, with the Buddhist monasteries owning large tracts of land with the peasants who cultivated it. Powerful landlords also increasingly limited the freedom of peasants, reducing them to serfdom. Later dynasties embraced the social and economic structure of serfdom, as was the case with the Song Dynasty (ca. 960–1279), and allowed it to flourish. Chinese religious authorities also held no moral reservations on the institution of serfdom, and like in Christian Europe, Buddhist monasteries had the most extensive holdings of serfs in medieval Chinese society.

That serfdom, in various forms, was practiced in societies as diverse as those of Europe, the Middle East, China, and elsewhere serves as something of a testament to its utility in the Middle Ages. Certainly seafaring peoples and nomadic traders of all cultures found less value in the tenets of serf systems, but agricultural societies with rigid social hierarchies appear to have found serfdom to be among the most suitable systems for addressing their economic and social needs.

■ Introduction: High Culture and Popular Culture

High Culture in the early medieval age is the description of the way people in ruler's courts in the cities and in the prominent social institutions behaved. It was the

culture spread by the great universal religions. While each region had its own flavor of High Culture, in general there were only a few High Cultures in the Mediterranean-Eurasian ec-

umene. Outside of that ecumene, where the writ of the great universal religions did not run and where urbanization was not so prominent, High Cultures were less important. Mesoamerica probably had a High Culture, as possibly did the Andean civilization. Within the ecumene there were at least two Christian High Cultures, while the Muslim world was more unified with a single Islamic High Culture. Likewise, in South Asia there was a (not well-unified) single High Culture. In China and the rest of East Asia, the High Culture centered on Chinese literary culture and Mahayana Buddhism. High Culture involved more than a universal religion; it also involved manners, morals, and elite patterns of behavior.

Popular culture in the early medieval age was not mass culture because at that time, there were no mass media to disseminate it. Rather, popular culture was folk culture and developed from the folk traditions of the country people. Popular culture was preeminently village culture, although in every city there were also varieties of popular culture. There were many folk cultures, with a different one for at least each linguistic and ethnic group. Folk culture was essentially very conservative, based on the engrained traditions of the folk, which changed very slowly. Folk cultures were very resistant to the blandishments of the new universal religions adopted by the urban elites in the early medieval age. Folk culture often did influence High Culture, but almost always in the long run it was the folk culture of the villages that was most changed in the interaction between city and village.

An Age of Faith—Religion and Popular Culture in Christian Societies, 300–630 CE

With the legalization of Christianity within the Roman empire in 312, the Church entered a new age of growth. To this it brought powerful ele-

ments of both High Culture—clerical, liturgical, theological, and dogmatic—and popular belief and practice, especially those of illiterate believers. In the years before legalization Church leaders had developed educational tools for raising children in the faith and teaching converts. Yet alongside orthodox doctrine arose popular religious understandings and rituals, usually founded on formal teachings related to healing, salvation, or damnation. Many of these were developed locally, often arising from the blending of pagan and Christian practices, such as St. Augustine's mother's practice of making food offerings for her dead husband. With the great fourth-century expansion of Christianity came a wide variety of converts in all parts of the empire. Waves of converts followed the preaching of the Arian Ulfilas among the Goths and other Germanic peoples, another with the conversion of the Irish, and again with that of Frankish King Clovis in the late fifth century, later still among the Anglo-Saxons. In each case Christian preaching and liturgies had to establish themselves within ancient and deep-rooted pagan cultural systems that often altered the face of mainstream Christianity in the process. Around 600 Pope Gregory I wisely recommended that missionaries disturb

Baptism of Clovis, a manuscript illumination from the Grandes Chroniques de France. Conversion to the Catholic religion was a supreme political event, emphasizing the paramount role of religion in early medieval society. (Gianni Dagli Orti/Corbis)

➤ GREGORY OF TOURS ON THE SHRINE OF ST. MARTIN IN TOURS, SIXTH CENTURY

“Who could ever investigate or know how many miracles either constantly happen or have happened by means of the dust or the wax from that place or by means of something else that someone could take from the tomb? . . . A man was so filled with faith that he attempted secretly to remove some relic from the saint’s church; but although he often tried, he was never able, as long as he did not act for the common good. He wished to return, and during the night he came to the rope that rang the bell. He cut a small piece from the rope with his knife and took it with him. Once he returned to his home, it bestowed health on many ill people, thus there was no doubt that whoever was worthy faithfully to kiss that relic escaped illness. Saint, behold what you offer to believers who seek your protection in particular.”

—Joseph P. Byrne

only those parts of a society or culture that directly offended Christian sensibilities.

The process of conversion was often formalized first by mass baptisms at the order of a king or other leader, while the teaching of Christian doctrine followed only slowly. It is clear that much in the way of traditional ritualistic magic, healing, and spirit conjuring remained quite active. Popular belief systems demanded tangible instruments of power as well as access to powerful spiritual forces, and the Church slowly and not altogether successfully replaced the shamans and druids with the clergy and saints. For Germanic converts the very strangeness of the Latin language and chant may have provided the appropriate aura of holy presence. Clerics declared that the old gods were demons and drove them off by exorcism, perhaps the most powerful magic that the Christian priest had in the eyes of new converts.

Personal and communal ties to traditionally revered dates and places remained largely untouched. As had their pagan ancestors, Christian communities continued to celebrate certain days of the year, such as the kalends or first days of each year and month, with feasting, processions, gift giving, singing, and even dancing. Christian leaders, however, realigned the meanings of these popular festivals to Christian ends, rededicating them to events in the life of Jesus or the saints and adding sermons to solemnize the day. To augment the chanted scriptural psalms used in liturgies and at festivals, people wrote pagan-style hymns with Christian themes and even sang old pagan hymns, perhaps mentally applying the words to their new religion. The Church also absorbed the old pagan geography of sacred hilltops, groves, pools, wells, shrines, and even temples, which were now associated with Christian holy men and women and miracles instead of with the demonized gods or pastoral spirits. Christian churches and shrines, often occupying old pagan sacred sites, replaced the old pagan temples and shrines as venues for rituals and feasts. These structures were decorated with old motifs and symbols given new meanings: the shepherd, the bird, vines, cherubs, and fish. Reclining erotic Endymion became biblical Jonah, and glorious Apollo morphed into Christ.

The popular cult of the saints grew among the faithful, and the Church quickly capitalized on its value and strength. The saints were people in heaven blessed by God and granted powers over such annoyances as disease, political enemies, heretics, and devils. Popular during their lifetimes, after death—especially if they died martyrs to the faith—saints took their place in God’s presence and could serve as advocates for those left below on earth. As such they continued in their miraculous ways, especially when a believer specifically prayed to them and even more so when prayers were offered at their burial places or shrines. Popular shrines quickly evolved into formal churches and were staffed by the clergy, but their appeal only intensified and spread. Physical remains, or relics, embodied the holy power of the saint and were of great value to those who possessed them. While the cult of saints included prayers and hymns, it lit-

erally centered on the shrines and relics, and there began a small but steady stream of pilgrims to the holy sites. Here vendors hawked simple souvenir images, medals, ampules of oil from lamps that burned before the holy tomb, and even bags of dust that had supposedly settled on it, continuing practices previously conducted at pagan shrines.

Christianity and Western European Cultures

Christianity was founded and developed its early forms in the eastern Hellenistic half of the Roman empire. In these urbanized, Greek-speaking, and philosophically minded regions the religion of Jesus acquired formal Scriptures and theological literature, a hierarchical clergy, structured liturgies, and an impulse to monastic asceticism. Before 312 it was a relatively minor cultural phenomenon, better known for its persecution by the Roman authorities than its influence on Roman culture. With Emperor Constantine's acceptance of Christianity after 312, the Eastern cult became a state religion (and later in the century the state religion), and both state and religion were profoundly affected. As the Roman state in the West gave way to Germanic kingdoms beginning in the fifth century, Christianity, in both its Orthodox and Arian forms, replaced Germanic

paganism as it had Roman paganism. This transformation was even more profound and long-lasting than that of the late antique empire.

In the empire Christianity's most obvious effects were seen in its impact on classical religion and philosophy. By its nature Christianity was exclusionist, denying validity to any spiritual or intellectual system other than its own. In turn, state paganism, Eastern mystery religions, and Greco-Roman philosophical schools were eliminated, although not before Christianity had absorbed elements of each: the iconography of divine rulership, liturgical details of Eastern religions, and Platonic understanding of reascent to God. Christian art owes much to its Greco-Roman matrix and proved to be the means through which late classicism was preserved. Likewise,

Baptism of Christ. Detail from the mosaic of the Dome of the Baptistry of the Arians, Ravenna, Italy, sixth century CE. Built by the (heretic) Arian Christian Ostrogoth King Theodoric, this religious structure was appropriated by the Orthodox Byzantine Exarch of Ravenna when Byzantine troops took the city in 565. ➤ A MIRACLE OF SAINT JULIAN

Gregory of Tours on the Power of St. Julian to Convert Pagans, sixth century:

“On the following night the priest also had a dream in which he saw that the images which the pagans worshipped were being destroyed by [invocation of] the divine name and were lying on the ground after being reduced to dust. Four days later when the pagans wished again to offer sacrifices to their gods, the priest sadly knelt before Saint Julian’s tomb, wept and prayed that the brightness of divine power would finally visit these pagans who were trapped in darkness, and that the blessed martyr would no longer allow his own foster children to be bound by their blindness, since he possessed the happiness of eternal enlightenment [salvation]. While the priest was praying immediately thunder rumbled, lightning bolts flashed, a storm that combined lightning and hail poured down, and everything was in chaos. The entire crowd of pagans rushed together to the shrine and knelt before the priest.”

the Church borrowed the secular state’s administrative structure: its notion of law, its hierarchy, and its geographical expression. Thus, as the Roman state disintegrated in Europe, it was replaced by parallel, if often rudimentary, organizations: the Germanic kingdom and the Christian Church, whether Arian or Catholic.

By the era of invasion (the fifth and sixth centuries), the Church’s sacred texts, theological writings, and liturgies had been translated into Latin, a language that now had to be mastered by at least the religious elite. Since civic schools had disappeared everywhere but Italy, monasteries and clerical schools, both formal and informal, were generally the sole providers of literacy. At first this education included classical Roman authors haphazardly, but by the ninth century Benedictine education included

major authors in most genres. Monastic scribes fed the demand for copies of both sacred and secular literature by monastic and episcopal librarians alike. Thus did Latin Christianity preserve some of ancient Rome’s literary culture. The acceptance of religious imagery, specifically in sacred and liturgical books, provided Late Roman, Germanic, and Celtic artists a range of opportunities to translate their artistic traditions onto vellum and parchment. Exposure of barbarians to Italian and Greek models proved transformative, and early medieval painting emerged from the synthesis. The Church’s insistence on formal, architectural worship space dictated the design and construction of more or less permanent churches in which large numbers could congregate. Throughout the area once ruled by Rome stood the remains or ruins of buildings that proved sufficient. When the Christian leaders had the will and the resources of the local people, new structures arose, sporting arched doorways and windows and simple trestle roofs. Where Roman remains proved more inspiring, and especially during the Carolingian age, locals raised much grander buildings. Cathedral and monastic churches revived the basilica style, while Emperor Charlemagne borrowed directly from the Byzantine style on display in Ravenna, Italy.

When considering the changes undergone by the various Germanic peoples during the early Middle Ages, it is hard to overestimate the effects of Christianity. The Church suppressed pagan beliefs and practices but picked up holly wreaths, mistletoe, and Yule logs. Although the Germanic divinities Tiu, Wodin, Thor, and Freya were eradicated, they remain hidden in plain view in the English Tuesday, Wednesday, Thursday, and Friday. The Church’s reliance on literacy prompted more worldly scribes to preserve their histories and pre-Christian tales in writing, as evidenced by Charlemagne’s order to preserve Frankish traditions and the work of the Anglo-Saxon *Beowulf* poet. When contemporary poets composed, they sometimes blended Christian elements into their tales of warlords and monsters, as in *Beowulf*, or viewed the Christian story through a warrior’s eyes, as in the Anglo-Saxon “Dream of the Rood.” The legal traditions of the Burgundians, Franks, and Lom-

bards also found their way into written form, as did Charlemagne's many new laws.

Christianity's moral law is founded on Jesus's assurance that God is love and that love should be the basis for all of a person's interactions, even with those one despises. Christians were called upon to meet offenses with forgiveness rather than retribution and to meet threats with self-sacrifice rather than the sword. The Christian heaven was entered through submission and obedience to God's law, not martial glory as with Valhalla. The Germanic societies of the early Middle Ages were not prepared to recast their cultures so radically, and religious leaders struggled to reconcile the endemic violence with Christ's call. Providing material support for the (generally) peace-loving clergy and pacifist monks was one way for the violent to atone for their acts. On the other hand, the Church could, and did, condone certain acts of violence, although these were universally defined as defensive and unavoidable.

Charlemagne's cultural program, often called the Carolingian Renaissance, celebrated the inextricable tie between the Catholic Church and the Frankish monarchy. The king was served by abbots, bishops, and even the pope himself, and in turn he patronized all of them on the basis of the tremendous role they played in drawing the Frankish nation up from barbarity. Like Gregory of Tours and the Venerable Bede, Charlemagne saw that true national unity and societal unity depended on the success of the Church.

Religion and Popular Culture in South Asia

With its first few centuries being marked by the reign of the Gupta dynasty over much of South Asia, the period from 300 to 1000 CE is marked by high levels of achievement in the areas of religion and popular culture. Many of the classics of Sanskrit literature were composed at this time, and the philosophies and practices that characterize Hinduism to the present day were consolidated and popularized. The intricate temple art, architecture, and classical Indian dance forms widely associated with Hinduism emerged at this time, as did classical Indian drama. Scholars typically regard this period as the Golden Age of India and also as the Hindu Renaissance. But it was also a golden age for Jains and Indian Buddhists, with both communities being highly productive in the development of philosophical concepts, literature, and temple artwork.

With regard to Hinduism, the beginning of this period marked the completion of the two great works of Hindu epic literature, the *Ramayana* and the *Mahabharata*. In the centuries to follow, these two epics would become the basis for numerous poems, plays, dance dramas, and works of art. Popular versions of both epics, in the vernacular tongues of the common people rather than the high Sanskrit of their original composition, were written in this period, making the stories and the lessons contained within them available to all. This was also the period of the composition of the *Puranas* (Ancient Tales) in which the deeds of the deities of popular Hinduism are recounted. Although Hinduism is typically defined in terms of adherence to the *Vedas*, it is not the primary Vedic deities, such as Indra and Agni, who are most prominent in Hindu devotional practice but rather the deities of the *Puranas*: Vishnu, Shiva, and the Mother Goddess, known by a variety of names such as Devi, Durga, Kali, Parvati, and Shakti. It was in the Classical Period that these deities assumed the prominence that they have had in Hinduism ever since.

Prior to this period, Hinduism is generally identified with Brahmanism, the early Vedic belief system centered on the ritual of sacrifice and the philosophical teachings of the *Upanishads*,

which would remain foundational for subsequent Hindu traditions. But in the Classical Period, Hinduism comes to be marked by devotional traditions centered on the worship of the popular Puranic deities: Vaishnava traditions centered on devotion to Vishnu and his various incarnations (most prominently Rama and Krishna), the Shaiva traditions centered on devotion to Shiva, and the Shakta traditions centered on devotion to the Divine Mother. The practice of devotion, or *bhakti*, becomes absolutely central to Hindu spirituality at this time, in contrast with the earlier Brahmanical traditions, which emphasize the correct performance of ritual action (karma) or the attainment of a higher knowledge (*jñāna*). Though the philosophy of *bhakti* is articulated in the *Bhagavad Gita*, a dialogue contained in the *Mahabharata*, and the *Shvetashvatara Upanishad*, composed before this period, it is at this time that *bhakti* emerges as a widespread popular practice that has a major impact upon Indian culture. Cultural expressions of *bhakti* that become prominent at this time are poetry, song, dance, drama, sculpture, and temple architecture.

Bhakti is closely connected to the aesthetic philosophy of *rasa* (taste), which seeks to evoke an intense emotional experience of beauty. The composers of *bhakti* poetry and literature and the artisans and architects of this period fuse the aesthetic and the spiritual, utilizing the experience of beauty evoked by their art to direct the emotions of their audience toward the divine.

In a related development, a movement known as Tantra emerges during this time, rising to prominence in the eighth century CE. Tantra takes the fusion of *bhakti* and *rasa* to a new level, systematically employing sensory experience to enable the practitioner to transcend the realm of the senses. Tantric practices and artworks that emerge at this time include the mantra, the yantra, and the mandala. Mantras are sacred verses that can be chanted aloud or meditated upon silently. The sound of the mantra is believed to purify, and chanting or meditating upon it can induce an altered state of consciousness.

A yantra is a geometric design that is an abstract representation of a Hindu deity, usually the goddess Lakshmi. A mandala, similarly, is a geometric design that depicts the sacred cosmos,

made up of various layers or levels of spiritual realization, with the highest stage of enlightenment being depicted at the very center of a series of concentric circles. The mandala is chiefly associated with Buddhism, and Buddhists were prominent in the development and popularization of Tantric practice, exporting it to regions such as Tibet and Nepal.

In addition to the Buddhist participation in and contribution to Tantra, the major developments in Buddhist thought of this period include the Yogachara, or Practice of Yoga, system, according to which the true nature of reality is pure consciousness, and the Buddha Embryo or Buddha Nature doctrine, according to which all beings, being of the nature of pure consciousness, have the potential for enlightenment, which is simply the realization of one's true nature through the purification of the mind. Both of these ideas would have a profound influence on the Zen tradition, when Buddhism was finally transmitted to Japan. They would also influence Hinduism near the end of this period, as they were adapted to Brahmanical thought in the early ninth century by the great Hindu thinker Shankara in his development of Advaita, or non-dualist Vedanta, though this is a controversial claim given the charge of Shankara's Hindu critics that his philosophy is merely Buddhism in a Hindu guise.

Finally, the Jains were as culturally active as Hindus and Buddhists during this era. Some of the most striking Jain temple art in India was fashioned during this period. It was also during this time that some of the greatest Jain philosophers, such as Akalanka, Samantabhadra, and Haribhadrasuri, composed their works, developing the distinctive Jain philosophy of relativity, which sees all philosophical systems as having some insight into truth.

Religion and Popular Culture in Japan

In many ways, the developments in religion and popular culture in Japan from 300 CE to 1000 CE reflect the transformations that accompanied Japan's transition from a society of localized rule based on kinship relations to a state centered on a heavenly sovereign and administered by an organized bureaucracy. In other important ways, however, religion as realized in the popular culture of lay believers outside of officially sanctioned temples and shrines often reveal movements independent of this shift toward centralization. Religion in popular culture draws from Japan's rich tradition of indigenous beliefs that developed over time and within numerous geographic settings. The introduction of Buddhism to Japan by Korean monks in the middle of the sixth century injected an already vibrant religious landscape with new ideas and practices. Religious life in Japan would develop into a unique culture combining diverse traditions.

The appearance of large burial mounds, or *kofun*, in the late third century corresponds to the rise of unified rule in the Yamato area. These mounds were built as graves for powerful leaders. *Kofun* construction spread throughout Japan in the fourth century, peaked in scale and importance in the fifth century, and continued into the seventh century. Issues of succession most likely dictated many of the rituals surrounding *kofun*. Furthermore, archaeological evidence suggests that ritual acts to keep evil spirits away played a prominent role in burial practices.

Belief in local deities, known as *kami*, formed the center of religious belief in ancient Japan. The term *kami* covers a broad range of meanings

➤ REEVALUATING KUKAI

The Buddhist priest Kukai (774–835) is without question one of the most popular religious figures in Japanese history. Traditionally, Kukai has been credited as the founder of the Shingon sect. In this standard narrative, the Shingon sect represents a rupture with Nara institutions and the beginning of a new age. However, recent scholarship by Ryuichi Abe reinterprets Kukai's significance. Abe claims that Kukai contributed to religion in Japan not as the founder of a sect but rather by establishing a new form of esoteric discourse. Although traditional scholarship portrays Kukai as rejecting Nara Buddhism, Abe argues that Kukai was able to succeed precisely because he cooperated with existing institutions. In particular, Kukai brought back esoteric Buddhist concepts such as mantra from China and used these concepts to create a theory of language that allowed the existing clergy in Japan to understand their own texts in a new way. In other words, Kukai gave the existing institutions the tools to unlock the secrets to teachings that previously had been beyond the scope of their understanding. Furthermore, this Buddhist discourse came to replace the Confucian discourse of the existing political system. The clergy, who formerly existed under the control of the state bureaucracy, was able to take responsibility for maintaining the cosmic order and for legitimizing the rule of the emperor. In these ways Kukai shaped the political and religious landscape of Japan for centuries to come.

—Bryan Lowe

including deities tied to natural phenomenon such as the sun and the wind, demons, and animistic spirits; deities from creation myths; and tutelary deities. In some ways, *kami* and *jindo* (the reading of the characters Shinto prior to the fourteenth century) have been defined as any non-Buddhist deity. Even this broad definition is problematic because the relation between *kami* and Buddhist deities has been renegotiated time and time again throughout Japan's history. It is best to understand the concept of *kami* as fluid and existing only in relation to a particular historical context.

Early beliefs viewed *kami* as unpredictable and malevolent. For this reason, people

Ishibutai kofun in Asuka, Japan, seventh century CE. This is the largest burial cave in Japan, with stones weighing up to 75 tons. The mouth of the crypt was uncharacteristically left uncovered as a rebuke to the sometimes hated Emperor Soga-no-Umake, who had imposed taxes thought to be extortionate. (Yoshitsugu Nishigaki/amanaimages/Corbis)

worshipped *kami* in order to prevent natural disasters and disease thought to be caused by the violent manifestations of *kami*. Both mountains and the sea became associated with *kami*, and some of the earliest altars have been found at mountain passes and on islands between Japan and Korea. Many scholars speculate that these island altars arose to protect against disease entering Japan from the Korean peninsula. Although it is difficult to assess the validity of this claim, it is easy to imagine the desire to appease wrathful *kami* residing in rugged mountain passes and perilous seas. By the sixth and seventh centuries, however, *kami* had become closely associated with local clans, with many clans adopting tutelary deities.

The popular spread of Buddhism in Japan brought about an abundance of unique religious expressions. One popular movement was mountain ascetic practices. These practices were diverse, but many incorporated both Buddhist and non-Buddhist elements. There is some debate over the extent to which thaumaturgic ambitions drove practitioners to asceticism, but there can be little doubt that many privately ordained monks set out for arduous practices in remote locations with the hope of gaining magical powers. In addition, practices such as divination, healing, and shamanism colored Japanese religious beliefs.

One illuminating source with which to view Buddhism as a living religion containing these diverse elements is the ninth-century collection of tales titled the *Nihon Ryoiki*, written by the monk Kyokai (or Keikai). Many of these tales focus on strange and wondrous stories, such as ones that recount faithful and diligent believers flying up to heaven and greedy and deceitful Buddhist antagonists suffering twisted mouths and painful rebirths. However, there is a method to the madness of these narratives. These tales communicate the laws of karmic causality and the Buddhist doctrine of the six paths of rebirth. In other words, Kyokai aims to elucidate the rules that govern even the most inexplicable events. In this way, the *Nihon Ryoiki* represents a logical description of the world. In addition to discussing the basic laws of karma, Kyokai also describes devotion to individual bodhisattvas such as Kannon, faith in the Lotus Sutra, and tales of ascetic monks.

The Buddhist landscape of the Nara (710–784) and early Heian (794–1185) periods is often associated with rites aimed at protecting the state, but beginning in the Asuka (ca. 500–710) period, local clans also became strong patrons of Buddhism, building clan temples and inviting monks to stay in their homes. Additionally, local groups of believers known as *chishiki* engaged in Buddhist activities such as sutra copying independent of the state. Finally, in the tenth century there was a rise of popular Pure Land preachers such as Kyoshin and Kuya who emphasized relying on Amida for rebirth in the Pure Land. In these ways, Buddhism was not only a religion that provided spiritual protection for the state but also played an important role in the private sphere. These Buddhist and non-Buddhist elements that appeared between the years 300 CE and 1000 CE would continue to shape the religious landscape of Japan for centuries to come.

Syria under Roman Occupation, circa 300–600 CE

After Egypt, Syria was the wealthiest province of the Roman empire. In the period between 300 and 600, unlike the rest of the empire, Syria experienced an economic upswing in spite of the relative decline of its older Hellenistic cities. Because of its prosperity owing to its successful social, cultural, and economic transition through late antiquity, Syria became the heart of the Islamic caliphate immediately after the Roman rule ended in 636.

Consisting of coastal plains, the hill country, the desert, and the Euphrates Valley, Syria's geography largely determined the lifestyle of its ethnically diverse inhabitants. The coastal plains were dotted with Hellenized cities. The Jordan and Orontes rivers cut through the mountain ranges, providing water sufficient for bountiful agriculture. Farther to the east was the Syrian Desert, not a typical sand desert of Arabia but a rock and gravel steppe that receives only up to five inches of rain annually. Even farther east was the Euphrates River, surrounded by the rich black soil of the floodplains, called Roman Mesopotamia, with no natural barriers against Sassanid Persia. Syria produced wine, olives, olive oil, grain, vegetables, fruits (especially apricots and lemons), and all sorts of nuts, including pistachios. The biggest problem for Syrian farmers was water. Syria's water supply was provided by the Jordan and Orontes rivers and by numerous springs in the hills that could easily be exhausted by overuse. River valleys, especially the hills surround-

Ruins of Palmyra in present-day Syria. Palmyra was a wealthy city in Syria, one of the most prosperous provinces of the Roman empire during 300–600 CE. (Franco Pecchio)

ing the Orontes River, contained hundreds of prosperous villages with solidly built stone houses and churches, so sumptuous that the early researches mistook them for aristocratic villas. Syria, however, escaped the fate of the Western provinces, where much of the urban aristocracy escaped the declining cities by moving to their rural villas. There was continuous building activity in the cities and in the countryside, especially under Justinian. Numerous cities of the coastal plains and the hill country, namely Beirut, Tyre, Sydon, Caesarea, Latakia, Antioch, and Beroea, manufactured world-famous purple dye, glass, and linen and wool cloth as well as a variety of metalwork.

The boundary between the arable and the arid lands was also a cultural divide between the settled farmers and the nomadic tribes of the desert. The two groups looked at one another with suspicion. Inhabitants of the coastal plains, the hills, and the Euphrates Valley used the donkey as the main beast of burden. Inhabitants of the desert used the camel.

There were three main caravan routes: one going south from Damascus following the Jordan River to Arabia; one going through Palmyra, in the Syrian desert, over the Euphrates into Mesopotamia; and another, also known as the Silk Roads that began at Antioch and passed through Beroea, Edessa, and Adiabene. The road continued across the border into Sassanid Persia and beyond. The border area had an extensive system of defenses known as *limes*. Recent archaeological and aerial surveys confirmed the

extent of the border system, which was as elaborate as the Rhine-Danube frontier in the West.

Politically, Syria was a part of the diocese of Oriens (after Egypt became a separate diocese during the fourth century). The governor of the diocese resided in Antioch and had the title “Comes Orientis.” The reforms of Diocletian divided the area into Syria Prima, Syria Secunda, Syria Maritima, and Syria Lebanesis. The diocese also included the provinces of Palestina, Prima, Secunda, Tertia. The bend of Euphrates area was known by the name Transeuphratensis. The Roman governor resided in Edessa.

Syria was highly urbanized and therefore Hellenized, especially the coast and the hills surrounding the Orontes River. The largest city in the area was Antioch, also the third-largest city of the empire, with approximately 250,000 inhabitants. Antioch suffered a devastating blow from which it never fully recovered in 545 when Khosrau I (531–579), the ruler of Sassanid Persia, invaded the area. As one moved toward the plains of Mesopotamia, the Hellenistic influence would fade, cities became less prominent, and the tribal way of life dominated the nomadic and seminomadic populations. The Christian Church, especially the numerous monastic communities, took over some of the political roles of the traditional urban elites as the Hellenistic cities grew smaller in late antiquity. Syria was home to personalities as diverse as the worldly pagan Libanius, an educated rhetorician from Antioch, and the austere and eccentric monks living on pillars, whose excesses and achievements in asceticism drew crowds from all over the empire.

Religious and ethnic boundaries often intersected in Syria. The largest ethnic and religious groups were Arabs, Arameans (often called Eastern Syrians), Armenians, Assyrians (often called Western Syrians), Greeks, Jews, Manicheans, and Persians. The practice of traditional religions (paganism) persisted, especially in the countryside, well into the sixth century even though Christianity had already become the majority religion by the fourth century. The spread of Christianity outside of Hellenistic cities was helped by the development of the Syriac alphabet in the third and fourth centuries, and indigenous literature began to flourish. The first works of literature were lives of saints. A specifically Syrian institution

was the holy man, the most famous being St. Simeon the Stylite. Living on a pillar in the hill country, Simeon not only organized a substantial monastic community but also served as an arbiter of local and tribal disputes. Holy men were also occasional intermediaries between the local population and the provincial and imperial governments. A similar institution arose within the Jewish community, where miracle-working rabbis among the so-called Amoraim (rabbis of the period 200 and 600) performed both religious and social functions.

Religious practices of the general population were syncretic, with borrowings across the ethnic and religious lines. Religious leaders repeatedly criticized and admonished the faithful to maintain communal boundaries, apparently without success. The Council of Chalcedon in 451 divided the Syrian Christians. The supporters of the council came mostly from the Hellenized urban areas and were called the melkites or the imperial church. The opponents, coming largely from the Syriac-speaking rural and tribal areas, were called the monophysites. Economically prosperous but culturally divided, Syria faced the Muslim invaders, who came in 636.

Age Groups, Education, and Initiation in East, Central, and Southern Africa

The agricultural and pastoral peoples of East, central, and southern Africa held puberty initiation ceremonies that involved long periods of seclusion. These were a form of intense education de-

signed for the purpose of making young people productive members of their respective societies. The entire community participated in public ceremonies; mature men (fathers and grandfathers) initiated boys, while mature women (mothers and grandmothers) initiated girls.

Bantu male initiation also included male circumcision, which was practiced in Africa for more than 9,000 years prior to this era. Only in the matrilineal regions of central and East Africa had male circumcision disappeared along with male initiation by 300. Female circumcision was not usually a part of female initiation except for northeast Africa, in areas heavily influenced by Southern or Eastern Cushitic culture.

In early Bantu history groups of adolescent boys were initiated together to form what was called an age set. These age sets served to organize men in ways that transcended blood and family ties. Women who were initiated together also formed less formal age sets. At the beginning of this historical era, age sets were universal among most of the Bantu-speaking peoples except those in southern Africa and in the matrilineal belt of central and East Africa.

Age sets had almost disappeared among most Bantu-speaking people by 1000. An explanation for this disappearance may be that as some societies began to centralize, new leaders were attempting to gather support based on their blood ties with members of their own lineages. The democratizing role of age sets could have eroded their potential power base.

In the Great Lakes region Bantu-speaking peoples eliminated age sets, as did their Southern Cushitic and Central Sudanic neighbors as they moved toward political centralization. The tradition survived, however, in regions such as Kenya and northern Tanzania, where a significant presence of Southern Cushites and Southern Nilotes retained their own form of age sets.

Northeast Africa developed differently since the Southern Nilotic peoples created unique forms of cycling age sets. In this region, men advanced through two life stages. The first was called *muren*, a young man's age grade, and the second, the *payyan*, was an elder man's grade. Because it took approximately 15 years until the next age set was initiated into the *payyan* stage of life, the young men remained together during

➤ EDUCATION—AFRICAN STYLE

Education is often seen as one of the few good things initiated by colonialism in Africa. Yet Africans had education for their children over 1,500 years ago. While it may not have included European history, children were taught practical skills for survival and were also taught about their history as soon as they were weaned. Children in agricultural systems learned about weather and botany, which included understanding plant cycles. Children in pastoralist societies became experts on cattle, their care, and their diseases. Gathering and hunting peoples started training their girls from an early age to recognize at least 2,000 types of plants, fish, insects, and small animals in addition to knowing where these things were located, what time of year they were plentiful, and under what conditions they were edible. Boys learned how to stalk and kill an animal as well as fish out of canoes. Initiation ceremonies at puberty were an African form of high school graduation whereby teenage girls and boys learned about sex education, parenting, psychology, traditional medicine, and cultural traditions. Younger children sat around a campfire listening to the elders tell the histories of their ancestors, stories about social mores, and religious stories such as origin myths.

—Christine Ahmed-Saidi

this period. Their primary responsibilities were to defend their community and raid other communities for cattle. This longer period of membership in the warrior age grade increased the ability of the Kalenjin to exert military pressure on their neighbors. They were able to expand into various areas along the Rift Valley in Kenya without changing their form of democracy based on seniority.

During this era, female initiation was central to all the matrilineal societies and to most of the patrilineal societies as well. By 300 in east-central Africa the most important ceremonies for the matrifocal Bantu-speaking peoples were the two-part female initiation rituals. A young girl at puberty was secluded and taught about her history and her clan's history and how to be a productive member of the society as a wife

and a mother. This education process involved a multidisciplinary approach. Schematic drawings were painted on large rocks or cave walls, ceramic figurines possibly numbering 400 or more were used as teaching devices, and unfired clay items were used to test the young girls' strength and agility. After marriage, when the young woman felt the movement of her first child, they celebrated a final ritual because she was no longer a *yadi* but instead was an adult and soon to be a mother. By 1000 these matrifocal peoples settled large parts of Zambia and brought with them the centrality of female initiation. Their matrilineal neighbors in Malawi, Tanzania, and Congo also celebrated long and involved female initiation rituals.

While agricultural and pastoral peoples used puberty rites as the basis for intense education, the gathering and hunting societies of the region continued their own education system, which probably dated back several thousand years prior to this historical period. Women started training their daughters from an early age to recognize at least 2,000 life cycles of plants, fish, insects, rodents, and other small animals. Prior to marriage and motherhood, young girls needed to know where to find food at all times of the year in all types of weather and regardless of various climatic changes. Their scientific knowledge of plant and animal life had to be extensive, since as adults they would produce 60–80 percent of the food. The young boys, meanwhile, were taught how to stalk and kill animals and to fish out of canoes. The Khoisan painted representational rock art, and the Batwa crafted schematic rock art as aids to spiritual and social education.

Education in the Era of Expanding Regional Civilizations

Education in literate societies in this era took several forms. The most elaborate and institutionalized school system of the age was that of China. In China there was a highly developed system of religious education, mainly Buddhist, but also a parallel system of state schools. Buddhist monasteries sometimes operated free primary schools, but they specialized more in higher learning, functioning somewhat as universities. Daoists also maintained similar institutions. Also in China, there were schools in many villages for children and adolescent boys. These schools were often partially financed by village associations or lineage groups, but almost always the parents were assessed a fee, which only a small minority could afford. In these schools the basic skills of literacy and numeracy were taught. Higher education to prepare candidates for civil service positions took place in provincial schools and also at a national university in the capital, Chang'an, or sometimes Luoyang.

In the late Roman empire, education was only somewhat less institutionalized than in China. In the Roman and Byzantine empires, as in China, elementary education was carried on in local schools, but these were by no means public and were usually supported by fees paid by the parents. In the Roman empire as in China, the wealthy often hired tutors to educate their children privately. Higher education in philosophy, law, and rhetoric during the late Roman empire was provided by special institutions, often at least partially supported by the government. These institutions were located in the chief cities. Preeminent among these were the Library at Alexandria, the Platonic Academy at Athens, and similar institutions in other cities. Classical higher education fell on hard times, however, with the triumph of Christianity in the Roman empire, especially in the fourth and fifth centuries. During these centuries and after, pagan institutions throughout the empire were closed or destroyed, including the Library at Alexandria. In 529, the Platonic Academy in Athens, the last classical institution of higher learning in the Roman empire, was forced to close by Emperor Jus-

tinian (r. 527–565), with its savants fleeing to exile in Sassanian Persia and India.

In 425, Emperor Theodosius II founded a Christian school of higher education, which evolved into the University of Constantinople. Designed to educate government bureaucrats and the higher clergy, the university did preserve somewhat the learning of classical Greece and Rome, but its emphasis was on promoting Christian orthodoxy.

The tradition of Greco-Roman science and philosophy continued at institutions in exile. In 353, a group of Nestorian scholars established an academy at Nisibus and later Edessa, Syria. There, these scholars continued the classical Hellenistic science and philosophy tradition for over a century until the intolerance of the Roman emperor Zeno drove them to seek refuge in the Sassanian empire in 489. The Sassanian emperor Khosrau I (r. 531–579) assisted them to found Gondeshapur, which became an influential institution of higher education with an attached hospital. This institution specialized in medicine and science and preserved most Greek and some Indian philosophy and science until the Muslims could absorb it in the eighth and ninth centuries.

The educational system in Muslim countries, though not nearly as institutionalized as those of China and India, helped produce a culture as uniform as that of China and more uniform than that of India. This culture extended through the whole vast territory of Dar al-Islam. Very soon after Muhammad's death, Muslim authorities recommended that Muslim boys memorize the Quran, starting as early as the age of seven (some sources say four). Boys met in the mosques to memorize, guided by a teacher. These mosque schools soon evolved into elementary schools (*maktab*), where literacy and numeracy were also taught. Secondary and higher education in religion, literature, and jurisprudence developed by a somewhat informal, noninstitutionalized system.

Students would seek instruction from shaykhs noted for their knowledge of religion and jurisprudence. These students would sit in a circle around the teacher, learning by rote the learned man's lectures. When the student had absorbed the shaykh's lectures sufficiently, he

would receive a certificate or diploma that would give him the credential to teach what he had learned. This diploma was the forerunner of the bachelor's degree in modern Western higher education. Gradually, these learning circles coalesced into regular educational establishments, which eventually grew to be madrassahs, similar to colleges in the West. One of the oldest and perhaps the first such madrassah was established in Fez, Morocco, in 859 by Fatima al-Fihri, the pious daughter of a wealthy businessman. Al-Fihri, like other founders of madrassahs and maktabas, left an endowment, or *waqf*, for the support of deserving scholars at the institution. Similarly, in 974, the Shia Fatimid rulers of Egypt founded in Cairo what is often reputed to be the oldest university in the Western world, Al-Azhar. Originally, Al-Azhar was a Shia institution, but when the Ayyubids took power in Egypt in the twelfth century, the university changed to a Sunni orientation.

Buddhist monasteries in India, China, and Southeast Asia maintained other primary schools. Some Buddhist monasteries, such as that at Nalanda in Bihar, India, evolved into renowned universities, where secular sciences as well as religious subjects were pursued. These were mainly in northern India, but the greatest was Nalanda. Nalanda was perhaps the largest and most important institution of higher learning of the era. With over 10,000 resident students, its fame reached throughout India, Southeast Asia, China, Korea, and Japan. It was a focus of Buddhist pilgrimages from all of South and East Asia. Nalanda's preeminence endured from the fifth century until its destruction in 1193 by Muslim invaders.

Throughout India, Brahman teachers conducted schools in their homes, and Hindu mathas conducted schools of higher education for more advanced study of Indian philosophies and religious studies. In nonliterate civilizations, little can be said about the forms of education that were specific to this era.

Muslim Education before 1000 CE

Before 1000 CE throughout the Islamic world, Islamic education presented an easily recognizable face. In spite of there being no centralized governmental or religious authority charged with maintaining education, there was a ubiquitous system with a high degree of uniformity. While boys were the usual students, there is evidence that some girls were educated, at least in the primary literary subjects. What we know of this system is derived primarily from the lives of scholars, so it may be biased toward displaying their preparation as the norm.

This system was composed of a normal course of study, common schools, and teachers. The types of schools and patterns of education were as follows. From age 5 or 6 to 14 a boy went to a school, known as a *maktab* or *kuttab*, that was not located in a mosque and was more than an elementary school for reading and writ-

ing, although that is what the name implies. After learning the fundamentals of reading, writing, and reciting, a student of ages 15 to 18 could move on to the mosque-based school, the *masjid*, that had been in existence as early as the eighth century and that taught *Adab*, the literary curriculum, and the Islamic sciences. In these schools, instruction in the literary sciences (grammar and poetry) necessarily preceded the study of the religious sciences (Quran, Hadith, and *fiqh* or jurisprudence), including some training in elementary logic and mathematics. There were circles of scholars and pupils (Arabic: *balqa*), and learning progressed to the advanced subjects. Finally, a student could study to become a scholar at one of the places for higher education where scholars could be found: libraries, bookshops, and literary salons, known variously as *bayt al-bikma*, *dar al-bikma*, *dar al-ilm*, etc., or simply called *majlis*. Alternatively, a young student could attach himself to a scholar for independent instruction. A good deal of this higher study consisted of reading the classical Greek mathematicians and philosophers in their Arabic recensions.

An enlightening, personalized description of this phenomenon is seen in Ibn Sina's *Autobiography*. This precocious student interested in philosophy learned reading and writing at home, where at age 6 his education continued under a tutor who taught him the Quran and Arabic literature; he was also sent to a greengrocer to learn arithmetic. Next he studied Islamic jurisprudence (*fiqh*) and began to study philosophy somewhere between the ages of 10 and 16. The only significant variation from the ordinary pattern is that Ibn Sina's father brought tutors to his house rather than sending his son to a school; this is simply a result of his social class. His story accords well with Islamic education as it was practiced everywhere in the Islamic world.

One peculiarity of the Islamic system was its international character. This was possible because of the relative uniformity of the educational system. A student from Islamic Spain who had received his primary education and learned some rudiments of logic was ready for the study of Hadith and *fiqh* in Cairo, Damascus, or Mecca. Those who desired higher education in the Islamic religious sciences often completed a grand

Al-Azhar Mosque and university in Cairo, founded in 972 CE. Al-Azhar was one of the first Muslim universities. Begun as a Shia institution by the Fatimids, it became a center of Sunni orthodoxy under the Ayubids. (Paul Cowan)

tour of the educational centers of the eastern Islamic world (Cairo, Mecca, Medina, Baghdad, and Damascus), gaining certificates (*ijazat*) in reading the classics of one or more of the Islamic sciences with noted teachers. While there were particular differences in legal opinion between the so-called schools of law, regardless of the school a student needed the same preparation to succeed in the study of it.

When one reads the lives of scholars, it is clear that unlike in our world the people with whom they studied are discussed, and there is almost no mention of the places in which they worked. Here we find that the norm was relational rather than institutional. In other words, the main way that a student acquired knowledge of philosophy, science, mathematics, and astronomy was by attaching himself to a teacher and reading the standard books under his guidance rather than going to a school.

While there were not degrees per se, scholars (*‘ulama*) were highly regarded and respected members of the community. Local rulers would compete to have the finest scholar they could get teaching in their capital.

Education in Early Medieval South Asia

Education in early medieval South Asia was closely tied to the institution of caste as well as to the monastic institutions of religious traditions, such as Buddhism. Although caste, as an institution, has fallen into disrepute in the mod-

WERE THERE UNIVERSITIES IN THE MEDIEVAL ISLAMIC WORLD?

Recent scholarship has focused attention on the character of higher education in the Islamic world and has opened a debate on the question of the nature and function of the *bayt al-hikma* of Baghdad. In older books there is generally a celebration of it as the precursor of the modern university. However, what we think of as a modern university existed nowhere before 1000. This shadowy institution carried out nothing like a university mission. Instead, it seems to have been a library complex where book acquisition, preservation, and study occurred. Such places seem to have existed in all the major cities of the Islamic world as early as the Umayyad caliphate.

This does not mean that there were no institutions for higher learning; however, the main goal of institutional instruction was in the religious sciences. While some secular educational institutions for higher education did exist, most were created after the end of the first millennium CE. Among them, in medieval Cairo there was a *dar al-‘ilm* created in 1005 CE under royal patronage dedicated to providing a place and means to higher study of secular subjects.

—Michael C. Weber

ern period due to the restrictions that it imposes on individual mobility and the social prejudices that have come to accompany it, the castes in early medieval South Asia were akin to trading guilds: highly specialized communities centered on particular occupations with highly valued knowledge and skills unique to themselves. Knowledge of specific occupation-related skills was passed from one generation to the next through the caste system: mining, metallurgy, weaving, dyeing, carpentry, and so forth. This system of highly specialized education led to a very high degree of development across a wide range of technologies, especially in engineering, minting, stonecutting, polishing, and carving.

More generalized forms of knowledge, such as writing, grammar, mathematics, medicine, and astronomy, were passed on, typically by Brahmins, in special schools, or *pathashalas*, typically reserved for young upper-caste males,

THE GREAT BUDDHIST UNIVERSITY AT NALANDA

Buddhist educational institutions were the ancient Indian equivalent of contemporary Ivy League universities. All fields of knowledge were taught, along with Buddhist systems of philosophy and meditation. Some of the major works of Buddhist philosophy were composed at Nalanda, which was also visited by the Chinese Buddhist pilgrim Xuanzang, who traveled to India in the seventh century CE to retrieve primary Buddhist texts. At one time, these ruins were swarming with students from all over South Asia who came to receive the knowledge for which this institution was famous.

—Jeffery D. Long

though this knowledge was also made available by ascetics from non-Brahmanical traditions, such as Buddhist and Jain monks. It is also evident that not all Brahmins uniformly held restrictive attitudes about the sharing of knowledge, as some orthodox Brahmanical texts would suggest.

Though the practice of medicine was generally seen as a low-caste profession due to the inevitable contact with polluting substances, such as blood and internal organs, that it involves, authors of works on medicine were often accorded Brahmin status. Among the important Sanskrit works on medicine that were composed and used during the early medieval period in India are Charaka's work on the medicinal value of certain plants and Sushruta's work on surgery, the latter of which is surprisingly sophisticated for an ancient work, including detailed accounts of successful brain surgeries (carried out in order to relieve pressure). Evidence suggests that Indian medicinal knowledge of herbs reached Europe, particularly the *History of Plants* by Greek botanist Theophrastus, which describes their usage.

Similar knowledge, contained in Sanskrit works, is evident in the fields of mathematics and astronomy (which was not distinguished from astrology, as was also the case in Europe during this period). The work of the Brahmin Aryabhatta is particularly distinguished in this regard. It was in India that the decimal system was first developed. With the invention of the zero, the calculation of very high numbers was

made possible, and it has also been speculated that the vast age and scale of the universe found in Indian religious texts—comparable to that revealed in modern astronomy—was a direct outcome of this invention. The so-called Arabic numerals and algebra, both of which were made known to Europeans through their interactions with Islam, are actually Indian inventions.

Linguistic knowledge, focused specifically on the intricacies of Sanskrit grammar and pronunciation, was also a highly developed field from an early date. The grammars of Panini and Patanjali, both of which were composed before the Common Era, displayed a highly sophisticated grasp of linguistic principles and became the standard guides to classical Sanskrit usage.

The strength of the Brahmins in linguistics, mathematics, and astronomy is due to the importance of these fields in the ritual performance of Vedic ceremonies. The correct use of Sanskrit was essential to the chanting and recitation of the Vedas in ritual contexts. Mathematics, particularly geometry, was important for the construction of the altars used in Vedic ceremonies. And astrology is used even today to calculate auspicious times for events such as weddings, the starting of a new business venture, the building of a house, and so on.

In early medieval South Asia, Buddhist universities had the advantage over most Brahmanical learning of being available to anyone interested in learning, with caste being no bar to education. Major Buddhist centers of learning, such as Takshashila (Taxila) in the far northwest and Nalanda and Vikramashila in the eastern half of the Ganges Valley, were the Harvard and Princeton, the Oxford and Cambridge, of ancient India. Even non-Buddhists sent their sons to these universities to receive training in general knowledge, such as literature, grammar, mathematics, and so forth. Brahmanical learning was made available at these institutions as were such topics as Buddhist philosophy and Buddhist meditation, for many Brahmins had become converts to Buddhism from an early stage of the history of the tradition. Buddhist philosophical and dramatic works were composed in Sanskrit, the elite language of classical learning in India up to the modern period, and students were trained in the whole range of ancient Indian knowledge.

Most education in early medieval India was centered upon men. This is true of the knowledge of trades, passed on through the castes, the Brahmanical knowledge taught at the *pathashalas*, and the curricula of the Buddhist universities. Though there is some evidence that, at an early period, Brahmanical education was available to women and there were also Buddhist educational institutions for women (Buddhist nuns), women were primarily educated at home by their mothers and other female elders in the local community, and this education was mainly focused on traditional family responsibilities.

Education in Europe

In the fourth and fifth centuries formal education in the Roman empire retained the forms and content developed during previous centuries. Local authorities supported grammar schools in Latin in the west and Greek in the east, private tutors served the children of the elite, and teachers of philosophy and rhetoric provided advanced training for young men interested in scholarly and public careers. Christian leaders in both the east and the west accepted the importance of classical education as a foundation for clear thinking and eloquent expression, ensuring that the tradition would survive.

Survival was most evident in the Byzantine empire, where elementary and secondary students first mastered Greek and then the Greek poets, especially Homer. Elements of mathematics and some natural philosophy rounded out the basic curriculum. Higher education continued to focus on rhetoric and philosophy and was institutionalized in the School of Constantinople, founded by Theodosius II in 425. Schools established by the patriarch of Constantinople in the

HRABANUS MAURUS ECHOES ST. AUGUSTINE ON RHETORIC AND EDUCATING THE CLERGY, CIRCA 850 CE

“Rhetoric is, as the ancients have told us, skill in speaking well concerning secular matters in civil cases. However, though this definition does apply to earthly knowledge, the topic is not for that reason foreign to ecclesiastical discipline. After all, any orator or speaker who wishes to treat the divine law adequately and skillfully in his teaching, or one who wishes to compose a literate and polished statement needs this skill; nor should one be considered a sinner who studies the art at the proper time. . . . The fact is that he is doing something very worthwhile if he studies it diligently so that he may be fitted to preach the Word of God.”

—Joseph P. Byrne

Joseph Miller et al., eds., *Readings in Medieval Rhetoric* (Bloomington: Indiana University Press, 1973), 125–126.

seventh century provided basic classical learning blended with theological training designed to prepare men for ecclesiastical careers. Although the founders of Orthodox monasticism tended to be accepting of humanistic studies, Greek monasteries early on abandoned a broad secular curriculum for language mastery directed toward scriptural and theological scholarship.

In the western empire education withered during the German invasions and collapse of classical society of the fifth and sixth centuries. While Ostrogothic Italy retained some of this Latin heritage, in most areas it was relegated to monastic settlements where command of Latin was necessary for Bible study and the Divine Office. Western monastic founders such as Benedict assumed literacy among the brothers, but soon it became clear that training had to be provided within the monasteries, and monastic schools—along with some other clerical schools—remained the only repositories of formal Latin literary education. By the eighth century the liberal arts provided a basis for religious studies in Benedictine schoolrooms, and Anglo-Saxon scholar-monks such as Bede and Alcuin

of York were the best-educated men of their generations. Alcuin went on to work as a scholar-in-residence at the court of Charlemagne, ruler of a Frankish kingdom whose leaders at least dimly understood the value of the classical tradition and did much to preserve it. With the disruptions by Vikings and others in the ninth century, literary education in western Europe was again nearly extinguished.

Western and southern Slavs and the Irish had remained outside the direct control of the Roman empire, but both cultures were transformed by Christian missionaries who transmitted, respectively, the Greek and Latin religious traditions. Both required literate clergy and monks, so education in at least basic literacy developed. From the fifth century Irish monasteries taught Latin, but Irish scholars tended to apply it directly to Scripture and theology rather than the broader classical arts. By the sixth century Irish monastic missionaries were traveling about northern Europe replanting the seeds of Christianity and literacy that their ancestors had received from the continent. In Slavic lands ninth-century Byzantine missionaries developed spoken Slavic vernacular into written languages and translated Scripture for the people. Here, as in early medieval western Europe, education remained largely in the hands of the Christian Church. In tenth-century Rus, however, literacy followed the conversion of the rulers and quickly penetrated downward, as testified to by large numbers of birch-bark letters by literate laity in Novgorod.

Education in China

Education is one of the most fundamental parts in Confucianism. In *The Analects*, a collection of homilies attributed to Confucius, it is said, “In teaching, there should be no distinction of classes.” In China, from the emperor to a common peasant, everyone recognized the importance of education. Basic education was most often completed in private schools, such as *si shu* (the private primary schools), *yi xue* (charity schools), and *shu yuan* (private academies of learning). Imperial school offered higher education. Guo zi jian, in the capital, was the central university for Chinese and foreign students. The civil service examination was used as one of the methods to select officials.

The private academies have existed in China through the centuries ever since the days of the Spring and Autumn periods (770 to 475 BCE) and flourished in the Han dynasty (206 BCE to 220 CE). Generally, when a boy was three years old his parents would invite tutors to teach him at home. Later he would be sent to *si shu* in the village. Otherwise, there were also *yi xue* in many temples and monasteries. They offered free courses to the public so that the children from poor families also had chances to study. Education differed for women and men. Women were educated in their families and rarely attended public schools. They were principally taught feminine virtue. Some women in rich families had opportunities to learn literature, history, calligraphy, music, and stitch work, among other subjects.

Shu yuan was a unique education form in traditional China that started during the Tang dynasty. Unlike public school, *shu yuan* was a kind of private school organized by outstanding scholars. It underwent rapid development in Tang and flourished in Song, the following dynasty, and persisted until the beginning of the twentieth century. It is estimated that there were about 30 such academies in the Tang period, and the number rose to more than 1,900 by the Qing period (1644–1911). In 717 CE Emperor Xuanzong called for scholars to collect and edit books all over the country. The next year, the imperial library was named *shu yuan*. Later on,

THE CHINESE CLASSICS, EDUCATION, AND GOVERNMENT SERVICE

The major texts for the civil service examination were the *Four Books* and the *Five Classics*. The *Four Books* includes *The Analects*, *Mencius*, *Great Learning*, and *The Doctrine of the Mean*. The *Five Classics* are the *Classic of Poetry*, the *Classic of History*, the *Classic of Rites*, and the *Classic of Changes*, *Classic of Spring and Autumn Annals*. There were many other texts used to adjust different requirements in different periods. After 690, the Tang dynasty empress Wu formally introduced the palace examination, and it became the last hurdle for examination candidates. They might face and have an interview with the emperor directly. The emperor would give the candidates political questions with bamboo slips, and the candidates would answer them with bamboo slips called *ce wen*.

Although many Tang officials were not selected from examinations, in subsequent dynasties the civil service examination developed as the most important avenue for attaining an office. Biennial licensing tests and triennial qualifying tests were regularly held in counties to choose eligible candidates for the triennial provincial examinations that were held once every three years. Then there would be the metropolitan examination held in the capital. Finally, a small percentage of graduates

could take palace examinations hosted by the emperor. Hanlin Academy is the government institution in charge of supervision of provincial, metropolitan, and palace civil examinations.

The civil service examination was a degree system. Candidates who passed a certain level of the exam would be given corresponding title and rank. Those who passed the provincial-level examinations were awarded licentiate degrees, which made them eligible for appointment at the lowest rank. Those who passed the upper level of examinations at the capital were awarded doctoral degrees. The top one finisher in palace examination was called *zhuang yuan*. In today's China, when a Chinese student receives the top score in an examination, he or she will be praised as *zhuang yuan*. And before some important examinations, the parents will buy *zhuang yuan* cake for their children for good luck.

However, the civil service examination was weakened in the late eighteenth century. Some scholars saw it as an obstacle that was holding China back from modernizing. The civil service examination lasted 1,300 years and was abolished in 1905.

—Yiran Zheng

more royal *shu yuan* were established in the capital city (Chang'an or, later, Luoyang). In one of them, *ji xian dian shu yuan*, the collection reached 53,915 volumes. *Shu yuan* was not just a library but was also an institution that elected scholars and gave political suggestions to the government. Afterward, scholars outside the palace adopted this name. At first, intellectuals called their own houses of book collection *shu yuan*. *Shu yuan* were usually located in beautiful scenic places near mountains, rivers, and bamboo fields and intentionally pursued a natural environment different from the mundane world. Later on, some scholars also taught students or gave lectures. As a consequence, *shu yuan* turned out to be a private academic place for learning. In wartime when the public schools were damaged, the private academies of learning were necessary amendments of the education system.

At the very beginning of Tang (618 CE), the government maintained central educational institutions. At the regional level there were county and prefectural schools, which were all financed by the state. In the capital city there was a central university for higher education called *guo zi jian*. In previous dynasties official schools were open only to the gentry. Beginning with the Tang dynasty, official schools became available to common people. However, people needed to pass certain exams and attain the lowest academic degree first. In schools, students studied history, literature, calligraphy, mathematics, medicine, and so on. In the central university students might be recruited to certain majors and could earn a doctoral degree in seven years. Every ten days, every month, and every year, the students in *guo zi jian* needed to pass a test so that they could continue to study. In the early Tang the number of students in *guo zi jian*

reached 3,000. During the Tang dynasty there was a great number of students who came from Japan, Korea, and other countries.

The civil service examination was the earliest completed examination system in the world. It tested both learning and intellectual acuity by a series of exams. Its original and basic purpose was to select the proper bureaucrats for the imperial government. This exam system was constructed in 606 CE in the Sui dynasty. In 622 the Tang emperor Gaozu announced that the exam was open to the public and that all educated people were free to take it. The candidates included both students who studied in local schools and students who were educated at home. When the first emperor Li Shimin saw students coming into the exam court, he said excitedly, “All the heroes under the sky are in my pocket!” To enter officialdom, the candidates would undergo both literary examinations and character evaluations. A person’s level of appointment would be determined by his performance during this process, including deportment, eloquence, calligraphy, and legal knowledge. In 702 CE Empress Wu Zetian, the only female ruler in Chinese history, constituted the other exam system for selecting military commanders. They were required to meet the physical qualification. At the same time, they were tested in horsemanship, the skills of archery, and using other weapons as well as in the art of war.

This examination system was not only an effective method to select bureaucrats for intellectuals but was also the ladder to success. Many

scholars pointed out that in traditional Chinese society entry into the ruling bureaucracy was the final goal for every man. Aside from civil service examination, it was hard for individuals to gain prominence and demonstrate their creative energies. Since the exams were open to the public and, to a large extent, were fair, they encouraged individuals to put forth effort in their academic studies and improved social mobility in Chinese society. Because of this, many commoners had the opportunity to move upward to higher class.

Through this system of education, orthodox values were diffused in China, and the Chinese empire developed a common culture. Many members of the general population studied the classics in schools and memorized the notions for the examinations and then were tested by the ruling class. The system of education, especially the civil service examination, effectively transmitted dominant values to large sections of society. Over time these values were also disseminated through public lectures, encyclopedias, almanacs, and the legal code. The existence of this educational and examination system ensured that the ruling class was grounded with a broad social foundation.

■ Introduction: Varieties of Material Culture

As in all other eras, peoples throughout the world were identified by and expressed themselves through material culture. Their great monumental architecture, such as the platform pyramids in Mesoamerica and among the Andean peoples, the great Buddhist monuments and Hindu temples, the Muslim mosques (particularly the Umayyad Mosque in

Damascus), and the Christian churches such as Hagia Sophia were statements of the power and glory of these cultures and religions. The palaces in which the rulers and other elites dwelt were designed to elicit the awe of the common people at the majesty of the elite.

Houses of commoners were usually small and built of abundant but cheap materials such

as sun-dried mud of clay between wood laths. Stoves and chimneys were rare, and the smoke from the hearth escaped through a hole in the roof. Sometimes cooking was done outside of the dwelling so the air in the house would be less smoky, but most houses were cold. The houses of early medieval commoners were nonetheless often charming and sometimes had a rustic beauty. Commoners often took pains to decorate their dwellings, sometimes painting symbols on the exterior, often on the lintel of the door. In many cultures, dwellings included a shrine to the ancestors, an icon corner, or a religious altar. Care would be taken to keep the objects there clean and polished.

Clothing was also designed to emphasize class differences. While the vast majority of the earth's population was scantily clothed in less-fine fabrics such as hemp, linen, ramie, palm fiber, or wool, some in India, the Muslim world, and the civilizations of the Americas enjoyed cotton. In the Andes, textile weaving of cotton and fine wool of the vicuna was a highly developed art, and some textiles made of these materials were treasured luxury items. However, during this period, silk was the most treasured fabric, and the production and commerce in this textile stimulated the economy of the Eastern Hemisphere.

One of the most ubiquitous types of material culture was pottery. All but a small percentage of human groups had pottery (although some, such as the Inuit and the Eastern Polynesians, whose ancestors had pottery, abandoned its manufacture and use), and all classes used pottery. Although pottery was probably the most common variety of material culture, in a few groups, such as the Moche of the Andes civilization, pottery making was a highly developed art form. For the Moche, clay pottery sculpture was what sculpture in stone or bronze was for peoples of Eurasia. Throughout Eurasia, porcelain was the most sought-after ceramic pottery and, like silk, was traded through most of Eurasia as well as much of coastal Africa.

The peoples of western Eurasia led the world in the production of glass and glass objects. After the fall of the western Roman empire, the center of glass making moved to Egypt and western Asia. Glass, which was used to produce most

of the same objects that were made of ceramic pottery, was difficult to make and was expensive. The possession of glass objects was a mark of status.

Metallurgy was a highly developed craft in many civilizations, and utilitarian tools and weapons as well as ornamental jewelry were made of it. The peoples of central and northern South America were especially skilled at producing beautiful ornamental objects of tumbago, an alloy of copper and gold with some silver. In Mesoamerica, where the art of metallurgy was adopted only late in this period, craftsmen carved fine ornaments of flint and obsidian.

Food was an aspect of material culture that involved people of all cultures in all ages. In all cultures, at least 90 percent of the population was involved in food production, and more were occupied in preparing it for consumption. Varieties of food reflected status. The more expensive harder-to-produce foods were consumed by the elites, while the lower classes ate coarser and cheaper foods. In this period, the cuisine of the Americas, Africa south of the Sahara, Mediterranean Eurasia, and South Asia were very different because of the different crops and domestic animals. During this period, the crops of India and Southeast Asia spread to China, the Mediterranean region, and Africa south of the Sahara, but the crops of the Americas would not be known in Eurasia and Africa until the late fifteenth century.

These were only the principal varieties of material culture in the early medieval age. There were many more.

Mound Builders and Other Agriculturalists in Eastern North America

What archaeologists delineate as Mississippian Culture actually had its origins with two civilizations that did not originate in the Southeast. The Adena Culture that existed between 1000 and 100 BCE originated within present-day Ohio, Indiana, West Virginia, Kentucky, and portions of Pennsylvania and New York. The Adena was a mound-building society that reached its zenith in eastern North America prior to the coming of the Europeans. The Adena Culture is considered by many archaeologists to be a precursor to Hopewell Culture and hence the more advanced Mississippian culture. Yet all of these cultures had in common the construction of earthen mounds.

Adena mounds were constructed on flat-topped hills to form circles, squares, and other shapes. They usually encompassed an area of about 350 feet in diameter. Moreover, these earthen mounds were usually built as part of the burial process whereby layers of bodies were deposited one after another upon the top of a

burned mortuary building. Prior to the construction of the mounds, offerings were made to the deceased and were composed of foods and cherished items that were burned along with the honored dead. Subsequent additions were made atop the previous layer so that over time the earthwork grew in size and prominence.

Archaeologists postulate that the construction of these Adena mounds required a small workforce. The Adena (primarily centered in Ohio) lived a semisedentary life (they altered their residence according to the seasons) and subsisted on hunting and food gathering as well as the cultivation of squash and other local starchy plants. These small seasonal communities nevertheless reflect the increasing sophistication and perhaps an increased social stratification among the Adena. Over time the Adena built more expansive earthen burial mounds, where archaeologists unearthed more and more impressive artistic objects such as jewelry, pottery, and clothing. These items clearly indicate an increasing population necessitating a more sedentary lifestyle as well as social differentiation among classes of people.

► EFFIGY MOUNDS

Effigy mounds appeared during the Late Woodland period (700–1050 CE) in Wisconsin, Ohio, Illinois, Minnesota, and Iowa. These mounds are thought to represent boundary control within both local and regional areas. Most effigy mounds are shaped like birds or terrestrial animals, and all mound groups have both celestial and terrestrial animal shapes present, signifying dual religious division.

Terrestrial animal mound frequency varies by location. Between 80 percent and 90 percent of bear and panther effigies are segregated from each other. This regionalization of terrestrial effigy types signifies political and territorial boundaries.

The ritual use of fire has been observed in many effigy mounds. Within certain mounds, unusual gold and yellow sandy loams as well as oxidized brick sand and red clay have been layered with local deposits. Altars and burials are marked by continuous layers of charcoal and decomposed organics. The effigy mound culture was brief but left behind striking landscapes.

—Melissa Halverson

The Great Serpent Mound in Ohio was possibly a product of the Adena civilization (1000 BCE–400 CE), but was refurbished by the Fort Ancient people in about 1050 CE. The mound is nearly a quarter of a mile long and varies in height from one to three feet. The heaped earth of which it was constructed was laboriously scraped up by hand, using moose antlers for shovels. (Richard A. Cooke/Corbis)

Hopewell Culture, commonly believed to be an outgrowth of Adena Culture, first emerged about 200 BCE and flourished until approximately 400 CE. Archaeologists debate its origins. One school of thought argues that this culture first appeared in Illinois and then spread to western New York and from Wisconsin to Mississippi and contained both the Canadian and American sides of Lake Ontario. But Hopewell Culture may also have started (according to some archaeologists) in western New York, where it grew and expanded southward to the Ohio Valley. There, these native peoples pursued the mortuary (mound-building) practices found among the more ancient Adena peoples. Other archaeologists, however, believe that Hopewellian dispersion originated from western Illinois and spread to southern Ohio.

Hopewellian people, like the Adena and late Mississippian groups, built elaborate burial mounds. The Hopewellians placed many objects in their burial mounds, suggesting the high rank of their buried dead. Both the size of the mounds as well as the buried objects indicate that Hopewell Culture possessed a highly social structure that delineated the status of each group (and person) and the division of labor.

This society consisted of, along with the hunters and food gatherers, metalworkers, artists, and traders. For the most part the Hopewell people resided in rather small communities and pursued both hunting and food gathering to sustain their villages. Fishing became an important activity to augment their diet derived from native plants and wild game.

The expanse of the artifacts unearthed to date by archaeologists suggest that the Hopewell people developed a vast trading network. Many artifacts indicate the extent of the trade for status goods relied on for their burial ceremonies, with these objects reflecting the status of the individuals buried both in their lifetime and at the time of their demise. Among the possessions found in Hopewellian burial mounds include cherished weapons and soapstone pipe bowls in the shape of beavers, frogs, birds, and human forms. From excavations archaeologists conclude that the Hopewellians were very adept at metallurgy, fashioning copper into axes, arrowheads, and trinkets.

Hopewell burial mounds that have been excavated suggest a degree of sophistication far exceeding their predecessors, the Adena. For instance, Cook's Mound (in Louisiana) is one of the largest mounds built by the Hopewellians. They buried 168 bodies within the platform and added another 214 bodies on the platform before covering the entire area with a huge mound. Their decline after 400 still remains a subject of contention, yet many archaeologists believe that the primary culprit was overpopulation, which put a strain on available resources.

The Mississippian Culture of the Southeast is considered to be an extension/offshoot of both the Adena and Hopewell cultures. Between 1 CE and 450 the peoples in the Southeast and the South built more and more massive burial mounds. Each varied in size yet signified an increasing population in the regions where the mounds were built. The movement to maize and bean cultivation between 800 and 1000 transformed the inhabitants of the South and Southeast. Settlements along the Mississippi River grew in size and number. The construction of substantial houses and platform mounds and the production of pottery all indicate an increase in their society's complexity. The Mississippians, while moving toward maize and bean cultivation, continued to hunt and fish as they had done in the past. By 900, larger Mississippian centers could possess populations in the thousands and were generally surrounded by defensive palisades. These larger settlements possessed a largely hierarchical society with a principal chieftain at the top. Cohakia (near present-day St. Louis) was the largest Mississippian center, with a population numbering between 30,000 and 35,000.

Farming Cultures in the North American Southwest

What archaeologists call the Mogollon Culture emerged sometime between 200 BCE and 200 CE along the Mogollon Rim's desert and forested highlands of southern Arizona and northern Mexico, and then it disappeared. According to Emil W. Haury, the Mogollon resurfaced as part of the Anasazi around 850. From archaeological evidence, the Mogollon people relied on rainfall and not on irrigation to obtain their sustenance from their fields.

It is nevertheless their settlements found in the colder, wetter, and more mountainous reaches of east-central Arizona as well as west-central New Mexico that have received the most scrutiny by archaeologists. The Mogollon people lived, at first, in small villages consisting of pit dwellings. These early pueblos normally had fewer than a dozen rooms where perhaps one or two extended families resided. The Mogollon evolution is characterized by five stages, the last ending about 500 years ago, and six regional variants. Mogollon communities as time progressed became ever larger so that by the time of Columbus they possessed pueblos that perhaps numbered several hundred rooms. This latter process would mean a more stratified society (hierarchy) and also a much more developed division of labor.

The Anasazi—"enemy ancestors" in the Navajo language, although denoted by scholars as the "ancient ones"—inhabited the plateau region of the present-day American Southwest. Many tourists each year visit the elaborate cliff dwellings found in Mesa Verde National Park, Navajo National Park, and Canyon de Chelly National Monument and the Great Houses of Chaco Culture National Historical Park.

Before 500 CE the Anasazi Basketmakers, so-named because of their intricately woven and decorated baskets, settled in caves and rock overhangs, cliff dwellings near streams or rivers. They located themselves along these canyon walls facing south to take advantage of the warmth of the sun during the winter months. However, like the Mogollon and Hohokam peoples, the early Basketmakers built small semisedentary villages in open areas.

For clothing the Anasazi Basketmakers wore fur or turkey-feather robes, string aprons, loin-cloths, and plant-fiber sandals. They subsisted on primarily corn, beans, and squash, which they grew in small garden plots as compared to the large-scale fields found in the later Anasazi pueblos, an example being Pueblo Bonito in Chaco Canyon. They augmented their diet through hunting (such as mountain sheep, elk, mule deer, and black bear) and food gathering. Women harvested wild crops such as amaranth, pinyon nuts, Indian rice grass, and sunflower seeds. The Anasazi Basketmakers were unaware of how to make pottery but were very adept at producing very ornate and sturdy baskets. Women cooked using these baskets by lining them with pitch where the food mixture was deposited, and then fire-hot stones were added to this mixture.

These baskets were fashioned into a wide assortment of sizes and shapes. They were utilized not only to transport possessions, to prepare meals, and for burial offerings but also to convey seeds and flour as well as to store grain and ceremonial items. To date, most early Basketmaker artifacts, mainly baskets, have been found by archaeologists within dry caves and rock shelters. The Anasazi Basketmakers' pace of evolution intensified by the middle of the first millennium. This is evidenced by the construction of larger villages, which possessed large storage and ceremonial structures. Some of the villages excavated by archaeologists in central New Mexico contain pit houses, comprising more than 50 in number. Although the later Basketmakers continued to hunt and gather food, they increasingly devoted more time to the cultivation of domesticated crops and their ceremonial structures. Like the later pueblo peoples, the Basketmakers began to build kivas, which contained a *sipapui* or small entrance where they believed the first people emerged from the underworld onto the surface of the earth.

While the Basketmakers' evolution lagged behind their southern counterparts, the pace of development hastened by the midpoint of the first millennium. They began to construct larger villages (with far greater storage capacity), signifying increased crop yields. For instance, in west-central Mexico archaeologists have unearthed a number of villages whose extent indi-

► THE CHACO CANYON—THE DEBATE GOES ON

Pueblo Bonito, which many archaeologists see as the capital of the Chaco Experience, was clearly a very important ceremonial center. Wolcott Toll has emphasized (and many other scholars have accepted his train of thought) that in order to understand Chacoan society, one must pay attention to the commonalities of modern-day Pueblo ceremonies. Pueblan society, like that of its historic past, is conditioned by the changing seasons. Corn consequently was a central aspect of Chaco society, as it is with the present-day Pueblos. We may surmise also that the rituals practiced by modern Pueblo Indians are similar or perhaps identical to those at the height of the Chaco Canyon era. In terms of the structure of the Chaco State (if this latter delineation is accepted), it is hard to unravel the pattern of office holding. Were positions hereditary? We really do not know for certain. However, the recent work of Brian Fagan (2005) offers a thorough study of the

archaeologists who have studied and continue to argue about the Chacoan political structure. He has noted that the only indication about the possible power of Chaco Canyon's political leaders emanates from Pueblo Bonito (particularly in light of research of excavated burial sites there). David Wilcox "believes Chaco was a small state administered from Pueblo Bonito, with territorial chiefs living in outlying communities." Fagan, on the other hand, embraces Frank Cushing's much maligned notion of a council of priests representing the six cardinal points. Whether Fagan and Cushing's view of the "Masters of the Great House" being the real model of the system of governance for Chaco Canyon's Pueblo Bonito is accurate remains a subject for speculation and argument. The accuracy of this view depends on whether the structure for Zuñi was actually a continuation of that followed by the Chacoans.

—John S. Leiby

cate a much higher population in the regions inhabited by the Basketmakers. Accordingly, these larger villages led to greater social stratification and more power in the hands of the elites who directed the evolution of these communities. Whereas the early Basketmakers had formulated an egalitarian society, increasingly the inhabitants of the ancient Four Corners region of the American Southwest evolved into a much more hierarchical society, although not on the scale that arose in Chaco Canyon.

As time progressed the inhabitants of what today is called the Four Corners area established more elaborate and lasting lodges that might be circular or rectangular in composition/structure. Over time both the residences and kivas of the later Basketmakers became larger, with inhabitants of each numbering several hundred people and each village encompassing 100 rooms and more than a dozen pit houses. Eventually in the late first millennium the Anasazi peoples of the Four Corners regions redefined themselves, as evidenced by the construction of the elaborate Chaco Canyon villages. There the Pueblo Anasazi constructed 11 villages encompassing between 500 and 100 rooms each. This so-called

Chaco Phenomenon represented a transition to even more elaborate villages and structures. Pueblo Bonito, in Chaco Canyon, grew larger and larger so that by 500 CE it was one of the most populated villages found in the canyon. Moreover, after 500 CE the Anasazi there began to substitute their pit houses for aboveground houses, which evidences their further development and refinement. These peoples continued to evolve, but by the mid-eleventh century they had reached their zenith.

In terms of the political/social system that developed among the peoples of Chaco Canyon and beyond, much debate among archaeologists has occurred and continues today and probably will persist indefinitely. Some scholars such as James Judge have postulated that the initial loosely configured farming communities of the Anasazi gradually grew larger, with Pueblo Bonito, for example, becoming the primary community in Chaco Canyon. The result was an increase in hierarchy. Field research over generations has unearthed differences in burial sites, which indicate in particular in Chaco Canyon that social stratification occurred. Many graves contain elaborate turquoise jewelry. Though still

debated, this circumstance would suggest that some people held greater social distinction and with it perhaps political power. If true with regard to the latter, this would support the notion of those who contend that what emerged with Chacoan people was a state. One of the more prominent of those supporting the idea of a Chacoan state, David Wilcox, has articulated the view that outlying communities became tributaries to Pueblo Bonito's more prominent families/clans. Yet another archaeologist, Steve Leskon, who researched the Chaco State Theory via the outlying communities with Chaco Canyon and its periphery, found similarities in their architecture, thus suggesting that Pueblo Bonito was not just a ceremonial center but in reality was the capital of the Chaco state. Whether there actually was a Chacoan state will undoubtedly cause present and future archaeological communities to continue to ponder.

Foods in the Era of Expanding Regional Civilizations

Food has been the most important aspect of material culture in any era. It is so vital that Christians, in their most important daily prayer, implored God to “give us this day our daily bread.” Food was also endowed with mystic qualities. Many religions demanded sacrifices of food as offerings to the divinity, and in some, including Christianity, one achieved communion with God by symbolically consuming his flesh and blood.

In most societies, consumption of rare or difficult-to-produce foods was a status symbol. Thus, in many parts of East and South Asia where rice was widely grown, the elites ate polished rice, while commoners typically ate less labor-intensive grains, such as millet or barley. In Europe, highly refined wheat bread was the fare of aristocrats, and the peasants ate coarser rye and barley bread. In northern Europe, sugar was very expensive and was used as a medicine, and even in the Mediterranean region, where it was sometimes produced, it was a luxury for the wealthy.

In most societies, celebrations and memorializations were the occasion for prodigious food consumption. Weddings and, less often, funerals were replete with feasting, as were religious holidays. Christians feasted at Easter and Muslims at Eid ul-Fitr, at the end of Ramadan. East Asians feasted during the Lunar New Year (Tet) and other celebrations. Indeed, the term “festival” derives from “feast,” when food is lavishly consumed. Just as people celebrated by feasting, they also gained religious merit by fasting. For this reason, Christians fasted during the season of Lent, and Muslims fasted during Ramadan. In many cultures, denying oneself food was a way to reach or communicate with the divinity.

Societies erected taboos against eating certain foods, and sometimes these taboos were reinforced with religious sanctions. In Muslim and Jewish cultures, preparation of foods was controlled by religious regulations. The Catholic Church forbade German and Scandinavian converts eating horsemeat because it was thought to be a sign of paganism. Pigs were eaten in many societies, but in Muslim and Jewish cultures, consuming these animals was forbidden. Dogs were considered food in China, most of the rest of East Asia, and by many groups in the Americas, but many other parts of the world viewed eating these animals with abhorrence. Insects, including silkworm larvae, ants, and grubs, were food in some cultures; in others the thought of consuming them evoked disgust. Most cultures that had domesticated cattle enjoyed milk and dairy products with the significant exception of China and other East Asian peoples. The great majority of peoples abominated cannibalism, though it occurred in most cultures in times of severe fam-

ine. Severe famines visited many lands several times in each century.

Though most societies forbade the eating of certain foods, almost everything edible was considered legitimate fare in some lands. Humans are, on the whole, omnivorous, particularly when starvation looms. As one Chinese general in this period remarked, everything, even leather, can be eaten if the cook prepares it correctly.

Almost all groups foraged, or hunted and gathered, either as their sole way of obtaining food or in addition to pastoralism or farming. Even in Buddhist groups, where hunting was frowned on, hunting was common. People have foraged for a wide variety of wild foods, anything edible that can be easily gathered including wild grains (wild rice), nuts (acorns, hazelnuts), insects (grubs, grasshoppers, ants, butterflies), fish (salmon, herring, anchovies), shellfish, crustaceans, marine mammals (whales, dolphins, seals), and terrestrial mammals, especially rabbits, large rodents (such as capybara), beaver, pigs, ruminants, deer, elk, moose, wild cattle, buffalo, bison, antelopes of many species, donkeys, horses, turtles, frogs, snakes, and birds (especially ducks, geese, turkeys, and the like).

For most sedentary societies, grain was the basic food. In China and India, various kinds of millets, wheat, barley, and rice were the staff of life. In West Asia, the Mediterranean region, and Europe, wheat, rye, or barley served the same function. In Africa south of the Sahara, the favored grains were various kinds of millet, except in the Inland Delta of the Niger, where African rice was favored, and in Ethiopia, where teff, a very nutritious seed, competed with wheat and barley. In the Americas, maize (corn) was by far the leading grain, but in the Andes, quinoa predominated in the highlands. In the North American Southeast, sunflowers and amaranth were the favored food until about 500 CE, when maize agriculture was spreading into that region.

Grain was eaten sometimes raw (green maize, parched wheat) or boiled, as porridge. The most widely consumed grain was rice, which was the higher-status food in East Asia, Southeast Asia, and much of South Asia. Brown rice (unpolished rice), though more nutritious than polished rice, was viewed as poverty food and was eaten only by the poor or the sick. The

elites, whose diets consisted largely of polished rice, sometimes suffered from beriberi, a disease of the muscles and nervous system caused by a vitamin deficiency. Rice was usually consumed boiled whole, not ground. Sometimes it was served as sticky rice balls, which could be eaten like an apple, but more commonly it was served plain and eaten with chopsticks (in East Asia) or with the fingers (in India).

Some grains were eaten crushed and cooked or boiled in soups or porridges. Often these were combined with vegetables and spices and, occasionally, meat. Quinoa, amaranth, and crushed maize in a form of porridge (*atole*) was often the chief food of the Mesoamericans, including the Maya, and the highland Peruvians. In Iran and West Asia a common food was soup or gruel made of crushed wheat or barley (*cous cous*), and in Tibet and central Asia pounded barley porridge (*tsampa*) was the daily fare. In China, India, and Africa south of the Sahara, the various types of millets were usually consumed as soups or porridges.

Many grains were commonly ground into meal or flour. Grinding grain was one of the most demanding and arduous tasks, usually performed by women. Sometimes, grinding or pounding grain was done in a large pestle mortar (especially in Africa south of the Sahara) in which several women collaborated. More often, grain was ground in quern (hand-operated mills) in Eurasia or metate (a type of horizontal mortar). In the Americas, maize was often boiled in limewater to soften it prior to grinding.

Flour, especially that of hard semolina wheat, was often made into noodles beginning early in the first millennium CE in China. In fact, the Chinese usually ate wheat and barley as noodles, seldom as bread. The Japanese often ate buckwheat noodles, which were served with green tea. The making of noodles spread from China westward across Eurasia in the middle of the first millennium CE. Muslim societies began to make and eat noodles before the turn of the first millennium, and the Italians adopted the practice from the Muslims shortly after 1000 CE.

Flour was baked into a variety of breads and cakes, both leavened (with yeast) and unleavened (flat bread, chapattis, tortillas). Bread in northern India and in Western societies achieved

➤ TWO MAJOR FOOD REVOLUTIONS

Agriculture and cuisine in most of the world's civilizations were radically modified with the Columbian exchange resulting from the European invasion of the Americas after 1492. In this biological exchange, Spanish and Portuguese explorers and merchants took maize, tomatoes, potatoes, peanuts, hot chilies, cocoa, tobacco, and many other plant foods from the Americas and spread them to all the shores they visited. Within a century, these new crops were being grown in Europe, Africa, India, China, and most of the other lands of the Eastern Hemisphere, where they transformed what had been the rather bland diet of the peoples of these regions.

Likewise, about eight centuries before that, another biological exchange enriched the cuisines of Africa, the Mediterranean region, the Muslim world, and Europe. This process began as early as the beginning of the Common Era but rapidly accelerated with the Arab conquests and creation of the Islamic empire. In this process, Arab soldiers conquered a vast territory, and Muslim merchants traveled to many more territories, reaching a large variety of ecological areas. Muslim conquerors and merchants brought watermelons from sub-Saharan Africa, apples from central Asia, and a large variety of tropical crops from India to enrich the diet of the Muslim world and subsequently Europe. Among these commodities were oranges and lemons, sugar, cotton, bananas, rice, eggplants, spinach, and other items, which enlivened the hitherto

impoverished menu of Mediterranean and West Asian foods.

These two biological exchanges may rank among the most important historical events ever.

This was nearly coterminous with the Medieval Warm Period, which also witnessed agricultural expansion in Europe and China. Although the more salubrious climate of the Medieval Warm Period may have some value in explaining the agricultural good fortune of early Dar al-Islam, there are other equally or more persuasive explanations.

The early medieval Islamic empire stretched about 6,000 miles around the globe and included a wide variety of climatic and ecological regions, from wet tropical to temperate forest and from Mediterranean climates with cool rainy winters and hot dry summers to areas with dry winters and monsoon summers. Arab armies and Muslim merchants became familiar with many foods and crops in this vast territory. High-ranking Arab commanders brought these crops to the areas to which they retired to assure themselves of a steady supply of these new foods, which in the beginning were regarded as rare delicacies. Within a relatively brief time, these erstwhile delicacies became staples of the Muslim agricultural portfolio. After 1000, these new Islamic crops began to diffuse into the Christian lands of Mediterranean Europe and later became commonplace in European cuisine.

—Wilfred J. Bisson

a status as the principal food. No meal was considered complete without bread; indeed, providing bread was the main preoccupation of the economic and cultural life of the people. The highest-status bread was finely milled and bleached white wheat bread, but most people ate other breads. In northern Europe, dark brown or even black rye bread was common, and in some areas barley, spelt, and other grains were used.

Unleavened flat bread was easily prepared by cooking dough directly on a hot surface, but more commonly leavened bread with yeast was demanded, requiring more elaborate ovens. In many villages, bread was made in communal ovens. In some areas bread baking was a seasonal occupation, with the bread made into hard, al-

most inedible loaves that were softened in ale or beer before being eaten. These loaves could be stored for months. In India, wheat and barley were eaten as various kinds of bread—chapattis, naan, roti, and others—depending on the region and method of baking.

In some parts of Southeast Asia as well as most of Melanesia, Micronesia, and Polynesia, taro, yams, breadfruit, coconut, and other starchy foods played the role that grains did in grain-producing cultures. The western Polynesians also began raising sweet potatoes, a crop they obtained from South America, but it is not certain that they got sweet potatoes before 1000 CE. In the Andean highlands, potatoes took the place of grains, while in Amazonia and the Ca-

ribbean, cassava, or manioc, both the bitter and nonbitter varieties, were a staple. In addition, most Native American agricultural peoples ate squash and pumpkins.

Grains do not provide a balanced diet. Their nutritional deficit was sometimes supplemented by animal proteins, but in most sedentary societies meat was not a common item in the diets of the mass of the people. Rather than meat, beans and other leguminous foods were consumed. In Europe and the Muslim lands, these legumes were peas and lentils. In Mediterranean lands, fava beans were also common. In India, a variety of legumes were consumed, but it was in China that soybeans almost completely replaced animal flesh as the source of protein in the diet. Manchurian tribes probably domesticated soybeans in the early first millennium BCE, and soybean cultivation then spread to northern China. In the late centuries BCE, soybeans were grown on most Chinese farms, and soybeans were consumed in a wide variety of ways: as a vegetable, as a drink, and, most ubiquitously, as soybean curd (tofu). Soybeans became a favorite and necessary food in China and all lands to which Chinese culture spread. Soybeans grew on less-fertile soils, the crop required less care than other crops, and they supplied all the nutrients that animal protein did. Indeed, soybeans were the wonder food in the Chinese diet.

The Mesoamericans and the people of the Andes enjoyed the most varied and, many say, the tastiest cuisine during this era. Tomatoes, potatoes, avocados, cocoa, and many other foods, during this time unknown in Africa and Eurasia, were staples in much of the Americas. Chile peppers, which characterize the cuisine of India and Southeast Asia and some regional Chinese cuisines and others in modern times, were unknown outside of the Americas before 1500 CE.

Meat of domestic animals was consumed in most areas. In most of Eurasia and Africa, these were various species of cattle, sheep, goats, pigs, chickens, ducks, and geese. In China, silkworm larvae were eaten after the silk was unwound from the cocoons. Native Americans had few domestic animals, though Mesoamericans as well as some other groups ate dogs. Mesoamericans also had turkeys, while in the Andes llamas and guinea

pigs were eaten. South Americans also had Muscovy ducks, and they adopted Araucanian chickens from Polynesian visitors, though perhaps not until after 1000 CE. Pigs were the meat most often consumed in China, Europe, and some Pacific Islands, but, as already noted, this meat was forbidden in Islamic lands where sheep, goats, and sometimes camels were preferred.

Milk and other dairy products were consumed in almost every Eurasian culture except China, Japan, and Korea. For the pastoral peoples on the steppe who milked cows, yaks, horses, and camels as well as sheep and goats, milk, cheese, butter, and cultured milk products such as yogurt, kefir, buttermilk, and kumis (fermented, slightly alcoholic milk, often from mares) were a most important and often chief part of their diet. The Bedouin of the Arabian and Sahara deserts consumed camel's milk. In most of the Muslim world, dairy products, especially yogurt, were a common staple. Most Europeans also used dairy products from cows, goats, and sheep, especially cheese and, except in Mediterranean Europe where olive oil was preferred, butter. In India, milk and milk products, especially from cows and buffalos, was highly valued and eagerly consumed. In India, sweetened yogurt (*lassi*) was a favorite drink, while clarified butter (*ghee*) was a common cooking oil. Eggs, which sometimes are classified with dairy, were an article in the diets of most peoples. In the Americas they were usually obtained by foraging wild foods, but in Eurasia (and Africa by the late first millennium CE) nearly every people had domesticated chickens.

All classes and ages in most societies commonly drank beer, ale, and other slightly alcoholic beverages. Indeed, much of the daily caloric ration was ingested with these beverages, and most peasants brewed beer or made wine. Beer brewing was women's work in many societies. Honey, grapes, other plants, and spices as well as hallucinogenic narcotics were sometimes used to flavor beer, but by the eighth century CE Europeans began flavoring beer with hops. Chicha, a drink made of maize, cassava, fruits, and coca leaves, was the equivalent of beer in the Americas. First the maize or cassava root was chewed by women and then was spat in a container and fermented, producing a drink with an

alcohol content of up to 6 percent. Fermented honey, or mead, had an alcoholic content of up to 20 percent and was prominent in northern Europe as well as Ethiopia. Attila the Hun is said to have died after a mead-drinking bout. In the Mediterranean regions of Europe, wine made from grapes served the same role that beer did in other parts of Eurasia. In China wine was also made from grapes, although wine made from rice was more common. In India and Southeast Asia, fermented sugarcane juice was common, though the Brahmin priests prohibited it. In Muslim lands too, alcoholic beverages, particularly wine, were widely consumed, though Islam forbade it. Before 1000 CE alcoholic beverages were made almost exclusively by fermentation. Distillation may have been discovered in India, but it had not yet disseminated to other lands.

Tea, which had been known to the Chinese since the late centuries BCE, became a preferred drink of the elite during the early centuries CE. Buddhist monks especially encouraged tea drinking and spread the practice to Korea, Japan, and other nearby lands. By the ninth century, tea was one of the chief items sold to the Arab and Persian traders at the port of Canton. The tea ceremony became a refined art, especially in Japanese elite circles.

A factor that affected diets worldwide was the necessity of preserving and storing food from the harvest, when foods were plentiful, to the dry season or, in the more northerly regions, in the winter, when scarcity might be more prevalent. Meat was preserved by drying, smoking, pickling in salt brine or vinegar, or, in the proper climates, freezing and keeping in cold storage.

Grain was stored in big baskets, huge ceramic pots, subterranean pits lined with stones, or granaries constructed to be as rat and insect proof as possible. Drying was often the method of preserving vegetables, as was pickling and fermenting. Fruit was sometimes dried, whereas vegetables such as cabbage were pickled all over northern Eurasia as sauerkraut or kimchee. Sometimes, special cellars were constructed to store foods at a constant cool temperature.

In all societies, obtaining, preserving, preparing, serving, and eating food was the most important part of any material culture.

Indonesian Contributions to East, Central, and Southern Africa

Between 300 and 1000 CE, small numbers of Indonesian immigrants arrived along the East African coast. These immigrants introduced new crops, new livestock, and even a new musical instrument to East Africa. From East Africa, these diffused to central and later southern African societies. By 300 CE or possibly a few hundred years earlier, a small group of Indonesian immigrants arrived in East Africa via the Indian Ocean and traveled along the coast, finally settling in Madagascar. One key source of evidence for this migration is that modern-day Madagascar is home to Malagasy, a language in the Austronesian family to which most Indonesian and all Polynesian languages also belong.

The Indonesian seafarers traveled first to India and then followed the monsoon winds to East Africa. The Indonesians may have settled for a brief period of time along either the Kenyan or Tanzanian coast and intermarried with local African peoples. By the end of the fourth century CE if not before they sailed south, crossed the Mozambique Channel, and arrived at the uninhabited island of Madagascar.

The Indonesian immigrants brought Asian yams, taro, bananas, and sugarcane, all of which could be reproduced by planting a cutting instead of seeds. Bantu-speaking peoples along the coast of East Africa were still practicing African yam cultivation; therefore, they easily added the new Asian root crops to their agricultural practices. Additionally, Indonesians had domesticated these crops in a region with a tropical climate much like the environment along parts of the East African coast, the Great Lakes, and the Congo Basin.

By the fifth century CE banana cultivation had spread rapidly into the inland parts of East and central Africa all the way to the Great Lakes region. Bananas became the most important crop for accumulation and surplus, and this

➤ BANANAS AND XYLOPHONES

Bananas, sugarcane, and the marimba (xylophone) are basic to the economies and cultures of Latin America and the Caribbean and were brought to the Americas by African slaves. These items were not African in origin but were introduced to the African continent by Indonesians who sailed along the East African coast over 1,500 years ago,

intermarried with Africans, and settled Madagascar. Once bananas and the xylophone were introduced to East Africa, they spread within a few hundred years to West and central Africa. Bananas even became the economic basis for several important African empires.

—Christine Ahmed-Saidi

Asian crop dramatically changed the economic history of these regions by greatly improving the productive capacities of Bantu-speaking societies.

The Indonesians also introduced chickens to Africa. By circa 1000 BCE, Bantu-speaking Africans had partially domesticated guinea fowls, which were allowed to forage for themselves. Chickens would have been raised in the same manner. Linguistic evidence indicates that by 1000 CE the chicken had spread throughout East Africa, southern Africa, and all the way to southeastern Nigeria at the mouth of the Congo River.

Southeast Asian immigrants also brought the xylophone to Africa. It is often referred to as the *mbira*, which is also the word for the thumb piano, an instrument invented by Bantu-speaking peoples over 2,000 years ago. But with the introduction of the xylophone, the term “mbira” began to refer to both instruments. The mbira is also used today in Afro-Latin music. The xylophone, which was brought to East Africa almost 2,000 years ago, became an important element in Bantu-speaking people’s music. This instrument later accompanied African slaves to Central and South America, where it remains a staple of local music.

Porcelain in East Asia before 1000 CE

Porcelain was one of China’s technological triumphs before 1000. Porcelain (or chinaware as it was sometimes called by the West) is a ceramic that is usually once-fired, which means that the body and the glaze are fired simultaneously. After the body is formed and finished it is dried, coated with a glaze, dried again, and fired. In the high temperatures (2,336–2,552 degrees F) of the kiln, both are fused together. Suitably modified with a flux, the material used to form the body of a piece of Chinese porcelain was often used as a glaze. The similarity in composition of the body and the glaze helped to produce a good fit between the two that reduced cracking. Thus, porcelain became a highly desired object because of its durability and unique thinness.

In the context of Chinese ceramics the term “porcelain” lacks a specific definition. This in turn has led to a debate as to when Chinese porcelain was first produced. Claims have been made for the late Eastern Han period (25–222 CE), the Three Kingdoms period (220–280 CE), the Six Dynasties period (222–589 CE), and the Tang dynasty (618–906 CE). Decorative arts scholars argue that the first true porcelain was made in the Chinese province of Zhejiang during the Eastern Han period. They also emphasize the presence of a significant proportion of porcelain-building minerals (china clay, porcelain stone, or a combination of both) as an important factor in defining porcelain and shards

Tang dynasty hanging scroll titled A Palace Concert shows the use of porcelain at a royal banquet. (National Palace Museum, Taipei/Werner Forman/Corbis)

recovered from Eastern Han kiln sites in Zhejiang. However, so-called porcelaneous wares or protoporcelain wares made using at least some kaolin and fired at high temperatures are known that date to well before the year 1000 BCE. Unfortunately, there is much that can divide porcelaneous wares and protoporcelain wares from true porcelain.

One of the first mentions of porcelain by a foreigner was made by a South Asian traveler around the ninth century (during the Tang dynasty) who recorded that “they have in China a fine clay with which they make vases which are as transparent as glass; water is seen through them. The vases are made of clay.” During the Sui and Tang periods (581–906) a wide range of ceramics, both low-fired and high-fired wares, were produced. These included the well-known Tang lead-glazed sancai (three-color) wares, the high-firing lime-glazed Yue celadon wares, and low-fired wares from Changsha. In northern China, high-fired translucent porcelains were made at kilns in the provinces of Henan and Hebei.

The city of Jingdezhen in Jiangxi was an important center for the production of ceramics in southern China since at least the early Han dynasty. The early wares were low-fired, but by the time of the Southern and Northern dynasties (304–589 CE) locally available raw materials were being used to produce a form of porcelain. In the year 1004, under the Song emperor Jingde, the newly renamed city of Jingdezhen

was established as a center for the production of imperial porcelain.

Within China during the Tang and Song eras abundant supplies of food enabled many parts of China to pursue technological and industrial interests. Porcelain wares were lighter and thinner and were highly prized for their translucence by the upper classes. Sets were usually produced for the wealthy, and of course a special unique set of pieces was gifted to the emperor. Porcelain was usually decorated with fine multicolored brushstrokes, and painted scenes appeared before 1000 CE. In the Tang period, with the rise of major cities such as Chang'an and with Buddhism becoming fully integrated into Chinese daily life, porcelain continued to become a reflection of an individual's wealth. Buddhist monasteries became repositories for merchant wealth and served as banks and warehouses for wealthy individuals. Some of the largest porcelain firms housed shipments in monasteries before sending them on to other destinations.

With the rise in wealth and status due to the reinstitution of the Confucian exam systems (*jinsshi* examinations), court life into the Song period saw major rises in kinds of wares that were produced for high-end tables. A variety of forms included plates and other kinds of dishes, but with commodities such as tea on the rise, porcelain production soared. Tea was such a major commercial crop starting in the Tang period that the government taxed it heavily. In order to set a proper table for scholar bureaucrats and other court officials, the government ordered vast amounts of tea-related forms that included cups, saucers, pots, caddies for tea leaves, and even waste bowls that were all made of fine porcelain. Images from the Tang and Song periods depict a variety of forms for such use, and since tea was seen as a pharmacological product, this would have a lasting impact on the porcelain production related to tea for centuries to come.

In the global context, the rise of new and powerful dynasties directly led to an increase in the demand for porcelain objects in both the Indian Ocean basin and along the Silk Roads that led to the Abbasid empire. Craft workers in West Asia challenged East Asian porcelain wares, but demand continued for these smooth, white chinawares. Routes traversed by Chinese junks and a

host of other traders from the Malay Peninsula to the South Asian coast and as far as East Africa carried porcelain to all of the destinations and those in between. Along with Arab dhows, junks were the best sailing vessels in the world. Equipped with watertight bulkheads, sternpost rudders, compasses, bamboo fenders, and rocket-propelled defenses, these ships enabled Chinese sailors and merchants to become the dominant force in the East Asian realm. Expanding into the Indian Ocean, Chinese junks also shipped porcelain because of their navigators' understanding and mastering of the seasonal monsoon systems. Although they did not intend to dominate the Indian Ocean, major connections did exist to create a symbiotic relationship with other traders who were not pirates. Archaeologists have excavated several sites along the coast of East Africa that yielded deposits of Song dynasty porcelain, so there is substantial evidence that porcelain became sought after by the communities of foreign merchants who congregated in cities throughout the Silk Roads. The development of porcelain and consumer demand continued into the Yuan period and set the stage for the production of Chinese export porcelain for the European market during the Ming (1368–1644) and Qing eras (1644–1911).

Glass in Early Medieval Civilizations

Glass in the early medieval world was primarily used for utilitarian purposes, religious observation, and decorative ornament. Advances in

glassmaking technology during the early Roman imperial era meant that glass went from being a precious, difficult-to-produce substance to a great commercial commodity within the vast network of trade routes spanning Europe, the Mediterranean, Africa, and Asia. The center of glass production was the eastern Mediterranean region of greater Syria (present-day Lebanon, Syria, Jordan, Palestine, and Israel), and this region continued to dominate the glass trade worldwide through the fifteenth century CE.

The area of greater Syria was strategically situated on the east-west trade routes, which allowed for exchange of goods as well as artistic influences. The sand in this area was superb for glassmaking. Glass was made of three key elements: silica (sand), lime, and soda (ashes of burnt plants). These ingredients were formulaically melted in large batches at temperatures of at least 1,150°C (about 2,100°F). The molten glass was then worked immediately or allowed to cool in large chunks. The latter, known as cullet, was shipped throughout the entire Mediterranean and Europe, where it was remelted in local workshops. This explains one reason why glasses made in the same period across geographic styles have the same chemical composition. It was much easier for a craftsman to reheat glass than to create his own.

For everyday usage, people continued to use glass much the same as they had during Roman rule. Kohl tubes were decorative glass vessels that held eye cosmetics in either paste or powder form and were one of the most widely produced vessels in the Palestinian glasshouses. They served both fashionable and practical demands, for the paste helped abate eye diseases. The form dated sometime from the ninth century to the fourth century BCE. During the fifth and sixth centuries CE kohl tubes began to get bigger and more decorative. The tubes doubled and then doubled again to four compartments with elaborately tooled ornamentation.

Not all forms of glass had such specific usage. Cone-shaped vessels were made in the late fourth to early sixth centuries across the eastern and western provinces of the Roman empire. Archaeologists have found evidence of their use as both lamps and drinking vessels, although not within the same household. The use of cone-shaped

► CAGE FLASKS

Cage flasks, sometimes called dromedary flasks, were a stylized form of the kohl tube that developed during the early Islamic period. Dating around the seventh to eighth centuries CE, these flasks were shaped as horses or camels carrying a caged jar or tube on their backs. Made entirely of glass, the vessels referenced early Roman cage cups, which exhibited a lattice network protecting the interior cup. These charming anthropomorphic flasks were widely available and may have represented the journey of oils and perfumes in glass vessels on the Eastern trade routes.

—Kelly Conway

Seventh-century Islamic cage flask. Glass-making was one of the most highly developed arts in the early Islamic world. (The Metropolitan Museum of Art/Art Resource, NY)

lamps probably originated in the Palestinian region in the mid-fourth century. They were filled with a combination of olive oil and water, which helped cool the glass and increased the optical effects. Glass lamps burned longer than clay lamps, an advantage in Jewish households where lamps could not be relit during the Sabbath. Along with household use, cone-shaped lamps were used in polycandelon to illuminate large spaces such as churches, tombs, and synagogues. In the western Roman empire the cone-shaped glass was used primarily for drinking rather than lighting. Elongated conical beakers without a flat bottom evolved from Frankish drinking customs in which a glass was never set down on the table.

Roman cultural influences declined as the western empire collapsed in the fourth and fifth centuries. Glassblowers used some older Roman methods, but slowly Germanic traditions influenced the style of glassware. One distinctive form that arose during the fifth to eighth centuries was the claw beaker. Often greenish-yellow or blue, these beakers had wide rims, small and disproportionate feet, and clawlike protrusions in two or three concentric rings. The claws were hollow so as to allow liquid to flow through them, which must have been a sight. Unlike metal or wood, glass did not affect the taste of wine. From the fourth century onward, drinking

vessels were the primary output for glassmakers in medieval Europe.

By contrast, in China ceramics, lacquerware, and bronze vessels were favored over glass for everyday usage. Domestic glass production was limited to beads, hairpins, bracelets, and cast-molded bowls. Chinese glassmakers used a formula containing lead and barium, making it distinct from any other glass. This also made it very thin and brittle with no ability to hold heat. By the Tang period (618–906 CE) this formula was abandoned in favor of a soda-lime composition brought with western craftsmen settling along the caravan roads. Certain forms, however, were specific to China and related to stone and lacquer vessels, such as flat-sided flasks. Although China was engaged in some glassmaking, items of Roman, Sassanian, and Islamic origin were more desirable and appeared in greater numbers over domestic glass.

The Silk Roads, a group of overland routes spanning 5,000 miles from the Mediterranean to China, became very important in disseminating commercial goods and cultural traditions. The Silk Roads, however, were not the only commercial routes to encourage such exchanges. The seafaring Vikings collected a wide variety of glass beads along their travels. Highly prized in Scandinavia, a wide assortment of shapes, col-

ors, and motifs demonstrated the broad territory covered by Viking ships. In Africa, coastal cities imported glass beads from India beginning in the fourth century CE, with beads flowing into the interior via African traders overland. Although little is known of domestic bead making in Africa during the first millennium CE, some evidence suggests that beads were manufactured as early as 600 CE in South Africa.

New ideas flowed into Japan, particularly during the Nara period (645–794 CE), from Byzantium, Persia, India, and China via trade routes. A number of glass objects from these cultures survive in the Shoso-in Treasure House, built in the eighth century CE as a temple to the Great Buddha. Some of the most common objects were beads (around 60,000–70,000) used on sashes, Buddhist utensils, furniture, sword handles, and imperial crowns. Glass was also used for cinerary urns and the revered *shari-ki*, a receptacle for relics that served to protect the temple.

While some regions adopted glass technology and objects into their culture, glass in India experienced a sharp decline from about the fifth to ninth centuries CE. Glass mentioned in Indian literature of the period revealed that it was very desirable as a substitution for precious jewels. Beyond this function, glass use and production were limited to bead making as an export good.

One of the most important influences on glass production during the early medieval period was religion. By the fourth century, symbols of Christianity were found on glass objects, sometimes mingled with older pagan iconography. Glass beads were common in the Roman empire although more typically favored by the lower classes. Around the fifth century CE, however, the church began to discourage the use of jewelry, including glass-beaded necklaces, for their pagan associations. Glass mosaics were used to decorate the walls and ceilings of churches and tombs, illuminated by hanging glass lamps. Glass-makers were even exempted from taxes and mandatory services, an order issued by the first Christian emperor, Constantine (272–337 CE).

From the fifth through the mid-seventh centuries, glass bottles and jars with Christian or Jewish symbolism were made in Syrian and Palestinian workshops. Important religious sites

were located in the Syro-Palestinian region, especially centered in Jerusalem. Increasing numbers of pilgrims to the area gave glassblowers incentive to create a souvenir trade. Workers blew the glass into full-sized molds bearing images of saints, crosses, birds, menorah, etc. Pilgrims could buy jars and fill them with oil, water, or dirt from the holy shrines and tombs visited along their route. Production of these souvenirs ceased soon after the advent of the Islamic period in 636 CE.

Buddhism was introduced to Korea by Chinese settlers and then to Japan by Korean immigrants during the fifth to sixth centuries CE. The popularity of glass beads, both imported and made domestically, peaked during this rise in religious practice from about 400–900 CE. In both Korea and Japan, the *kogok* and the *magatama*, respectively, were among the first type of glass made in both countries. This comma-shaped bead arose as a sacred symbol, in the yin-yang emblem of Korea, and as part of the three royal emblems in Japan (sword, mirror, and *magatama*).

Glass-making traditions in the greater Syrian area continued to evolve during the Islamic period. While the Islamic caliphates did not patronize the glass industry, the assimilation of Islamic ornament from other media such as textiles and calligraphy worked its way gradually into decorative glass. The widespread influence of Islamic art would later influence the Europeans, particularly the Venetian glass industry during the Renaissance.

Development of Moche Mold-Made Ceramics

From approximately 400 to 800 CE, Moche potters living in the valleys along Peru's northern coast produced an amazing variety of molded ceramic vessels ranging from portrait jars and stirrup spout bottles to whistles and dippers. Many of these were elaborately painted with complex scenes featuring anthropomorphic deities, humans, plants, and animals.

Potters hand modeled their ceramics during phases I and II (100–400 CE) of the Moche ceramic typology developed by Rafael Larco Hoyle, but beginning in Phase III they developed press molding and stamping techniques that made it quicker and easier to produce multiple copies of objects with three-dimensional or low-relief decorative elements. Most molds were two-piece, but potters frequently used one-piece molds for figurines and whistles; some complex sculptured forms made use of multiple molds. Potters made molds by packing clay around a mold matrix (a ceramic form made exclusively to produce molds), an already existing vessel, or other objects such as a warty squash. They sectioned

the mold into front and back halves while the clay was still wet and then waited for the two halves to dry completely before removing them for firing. Unlike ceramic vessels, mold matrices were unpainted, had thicker walls, frequently opened at the top and bottom, and possessed a vertical groove along the side that served as a cutting guide for the potter sectioning the mold under construction.

Molds facilitated the production of elaborate portrait vessels of individual Moche elite. In a survey of portrait vessels, Christopher B. Donnan determined that the faces of over 75 of 750 individuals appeared on 2 or more portrait jars, while many individuals appeared on 15 or more such vessels. Even though numerous portraits were produced from the same mold or molds made over the same matrix, potters nevertheless achieved variety by altering headdresses, adding nose and ear ornaments, incising facial features, or smoothing out unwanted elements. Moche potters also depended upon molds to increase production levels of mundane utilitarian wares needed for domestic and storage purposes.

■ Introduction: Literature in the Age of Expanding Regional Civilizations

Early medieval literature reflected the age's preoccupation with religion. Seminal religious works were produced in every society, and here we can mention only a few. India was the fount of a vast outpouring of religious literature, much of which influenced the religion of other cultures. In the fourth century CE, during the Gupta cultural florescence, Indian

scholars cast what has been called history's longest religious work, the epic *Mahabharata*, in its finished form. Gupta writers also rendered the Puranas, religious histories in the form that they have come down to us.

From the fourth to the tenth centuries, India was the arena for religious rivalry among Jains, Hindus, and Buddhists, all of whom wrote apolo-

getics for their traditions. Among the Buddhists, two are preeminent: the third-century Ashvag-hosa, whose *Life of Buddha (Buddhacarita)* and *Awakening of Faith in the Mahayana* became important works in the Mahayana wing of Buddhism. The Theraveda tradition found its defender in the fifth-century Buddhagosa, whose *Path of Purification* is still read by many. Bhakti devotional Hinduism found its expression in the Tamil south of India in the poems and songs of the 75 bhakti saints (seventh to tenth centuries), and Hinduism was given its modern formulation in the *Bhāṣyas* (commentaries) of Shankara.

In China, as in India, religious rivalry occurred, but by the fourth century, Buddhism had triumphed over both Confucianism and Daoism. The chief religious works in Tang China were Buddhist. Chinese Buddhist works included many canonical scriptures, such as the *Pure Land Sutra* and the *Perfection of Wisdom Sutras*.

In the western part of the Afro-Eurasian ecumene, Christian religious literature included the works declared canonical works of the Christian New Testament as well as numerous noncanonical works that were suppressed. In addition, Christian religious literature during this era included the writings and sermons of Ambrose as well as the works of Jerome (the *Vulgate*, the most important Latin translation of the Christian Bible), Augustine (*City of God, Confessions*), and the *Apophthegmata (Sayings of the Desert Fathers)* by Anthony.

Muslim works including the Quran, the hadith compilations of al Hajjaj and al Bukhari, and the tenth-century Shia work *The Peak of Eloquence*.

Nonreligious literature of the age was largely of two genres: popular folktales and court literature. Little of the folk literature has survived, as almost all was transmitted orally. Of the court literature, the work of the Sanskrit authors of the Gupta age (fourth to early seventh centuries) stands out. Kalidasa was the literary giant of the Gupta age, and he is often said to have been India's greatest author. His dramas are classified with the works of a very few authors in human history, such as the seventeenth-century English playwright Shakespeare. Kalidasa's *Recognition of Shakuntala (Abhijnanasak)* is regarded as India's greatest play and is the inspiration for

many modern Indian films. Sanskrit plays and poetry were highly regarded in early medieval royal courts; even Emperor Harsha (r. 606–647) delighted in writing and producing Sanskrit plays. In southern India, secular Tamil literature was produced from 300 to about 600, when the religiosity of the bhakti movement replaced it. This literature included *Cilapatikaram*, the great epic of the Tamil people.

In China during this age, lyric poetry dominated nonreligious literature. The two great Chinese masters of lyric poetry, Li Po and Du Fu, flourished during the very creative high noon of the Tang dynasty (the first half of the eighth century), and their fame endures to the present. In present-day China, schoolchildren still recite Li Bai's and Du Fu's poems.

In the middle of the first millennium CE, the Indian collection of folktales and animal fables known as the *Panchatantra* reached its final literary form. Tales from the *Panchatantra* subsequently spread west and appear in that great collection of Persian and Arabic stories known as the *One Thousand and One Nights*, or *Arabian Nights*. They also influenced Ferdowsi's (tenth-century) great Persian literary epic *Shahnama*.

The relationship between the tales in the *Panchatantra* and the comparable *Darofify* and *Darofipy* cycles of tales in the oral literature of the Malagasy people of Madagascar is unclear.

The literature, both religious and nonreligious, of Muslim lands in this era was usually written in Arabic until the ninth century, when a new form of the Persian language, Pahlavi, written with the Arabic alphabet, began to be widely used. From then on, most Muslim religious literature continued to be in Arabic, but scientific, philosophic, and historical literature in Muslim lands was increasingly written in Persian. Early Arabic literature, both religious and secular, more often than not took the form of poetry, and this genre was also prominent in Muslim Persian literature.

Christian literature of this era was overwhelmingly religious, as discussed earlier. Partial exceptions were some Byzantine and West European historical writing, such as the *Anecdota* of the sixth-century Procopius, the *History of the Franks* by Gregory of Tours, and the *Ecclesiastical History of England* by the Venerable

Bede. In Byzantine courtly circles, epigrammatic poetry was a favored genre.

In Japan and Korea, after their adoption of much of Chinese civilization, courtiers and other members of the upper class normally wrote Chinese, using Chinese literary forms. But at least in Japan a new type of literature arose, written by aristocratic women using Japanese syllabary script as well as Chinese characters. The most memorable work of these aristocratic women is *The Tale of Genji*, acclaimed by many scholars as the first and the greatest novel in human history.

During this era, literature in sub-Saharan Africa and the Americas was almost completely oral except in Mesoamerica. The written literature of the Mesoamericans, particularly the Classic Maya, is only now, after having long been occluded, being read.

Chinese Literature

The Northern and Southern dynasties (317–589 CE) and the Tang dynasty (618–907 CE) were two brilliant periods for Chinese literature. In the Northern and Southern dynasties, the chaos of frequent wars engendered decadent and over-subtle characteristics in composition and also stimulated the popularity of anchoretic poetry.

Li Po, renowned romantic poet during the Tang dynasty in China. (The British Library)

At the same time, as a conclusion of previous literary achievement, literary criticism and literary anthologies were flourishing. The Tang dynasty was the golden age of Chinese poetry. Tang poetry was preeminent because of an unrivaled position in both its quantity and the quality. The eighth-century writers Li Po and Du Fu are the two greatest poets in China's history.

During the Northern and Southern dynasties, the empire was divided into several short-lived kingdoms. It was common for one person to live through several dynasties. Wars took place everywhere and frequently. With experiences in wars, intellectuals felt the fragility of life, the impermanence of fortune, and unexpected fate. The feeling of the individual's powerlessness engendered a tragic mood in their writings. "Medicine" and "wine" became two major key words in poetry. Poets used medicine to cure their injured bodies and used wine to heal their wounded spirits.

In addition, anchoretic poetry (poetry of anchorites or hermits), a new trend, became popular. Because of the impact of war and the influence of metaphysics, intellectuals treated life and death imperturbably. They preferred escaping from society and living a solitary existence. Tao Yuanming (365–427) is a highly admired idyllic poet who spent almost half of his life as a hermit poet. Tao's beautiful long poem *Record of Peach Blossom Fount* (*Tao Hua Yuan Ji*) is a tale of a fisherman who lost his way and accidentally found a village in the mountains with masses of peach blossoms. In this isolated village, people keep primitive purity and rustic virtue. The fisherman was treated warmly and saw a peaceful and affluent society. "Old and the young are all happy," he exclaimed. After returning home, the fisherman could no longer go back to the peach blossom village; he had forgotten the way. In this poem Tao described an ideal world, so in Chinese culture "peach blossom fount" is the equivalent of Utopia. This idiom is even used today.

From the fifth to the sixth centuries, literary criticism was thriving. The most important works of literary criticism were *Fu on Literature* (*wen fu*) by Lu Ji, *Evaluations of Poetry* (*Shi Pin*) by Zhong Rong, and *The Hermit of the River Canglang* (*cang lang shi hua*) by Yanyu.

► LI PO AND DU FU—DAOIST HEDONIST AND CONFUCIAN MORALIST

Li Po (701–762) is the greatest Chinese poet. About 1,100 of his poems are extant. In his unparalleled poems we can find extraordinary imagination and expansive eloquence. He is called “Immortal Poet” and “Immortal of the Wine-cup” as well. Du Fu wrote a poem to describe his friend: “A hundred poems per gallon of wine,—that’s Li Po. Who sleeps in the taverns of the market of Chang’an, The son of Heaven summoned him, and he could not stagger on the boat, said ‘your servant is indeed an immortal in his wine.’” Being a Daoist Hedonist, Li Po’s writing and his life both showed the spirit of freedom. In one of Li Po’s poems, “Bringing in the Wine,” he wrote: “Oh, let a man of spirit venture where he pleases. / And never tip his golden cup empty towards the moon! / Since heaven gave the talent, let it be employed! / Spin a thousand of pieces of silver, all of them come back!” Having grown up in Sichuan Province, he later traveled and wandered around the country and wrote a great number of landscape poems. Being a romantic poet, he likes to use hyperbole in his poems. In his “Watching the Lu Mountain Falls,” Li describes the fall as “the torrent dropping three thousand feet, / straight down to the valley floor, / I think it must be the milky way / spilling to the earth from the heavens.”

Du Fu (712–770) is called “the Sage of Poets.” He was born in Henan Province. If Li Po’s poetry offered romanticism and Daoism, then Du Fu, in contrast, represented realism and Confucianism. Du incisively criticized social problems and spoke out against injustice. His words “Behind the gates of the wealthy, / food lies rotting from waste / Outside it’s the poor / who lie frozen to death” reflected the decline of the Tang dynasty that he witnessed. Around the rebellion of An Lushan, Du composed his best-known series of poems: the Three Officials and Three Leaves. In “The Official of Shihao,” Du told a miserable story: When Du came to Shihao village and stayed, he witnessed an official trying to catch someone after dark. The old man in the house climbed over the wall and fled. The old woman sobbed bitterly. Their three sons were all in the battlefield, and one had just written home and told them that the other two sons had died recently. In order to protect her husband and grandson, the old woman begged the official to take her. Du Fu’s touching poems reveal his intense love and sympathy of the people and the country. Fourteen hundred of his poems exist today and are regarded as “the mirror of his time.” Therefore, his poetry is called “historical poetry,” and he is also called a “poetic historian.”

—Yiran Zheng

These critical works have come down as historical masterpieces. Liu Xie (465–520) composed the most important work of literary criticism, *The Heart of Literature Carves Dragons* (*wen xin diao long*). Liu’s great work consists of 50 chapters. He wrote that literature is integral to the nature of things.

In the Tang dynasty, Chinese poetry reached its maturity. Tang poetry combines alternating tones and rhymes in accordance with strict rules.

In Tang poetry, there were many different genres. Wang Wei and Meng Haoran were good friends and prominent poets in the genre of landscape poetry. Their poems usually portray a beautiful and quiet scene and convey peaceful emotion. Frontier fortress poetry was made known because of Gao Shi and Cen Cen. They traveled along the far edge of the country and recorded their observations and moods. The

Han Meng genre takes its name from Han Yu and Meng Jiao. They were noted for the extreme care with which they selected the precise words to convey strange and exotic images.

Wang Bo, Yang Jiong, Lu Zhaolin, and Luo Binwang are remembered as the “four outstanding poets in early Tang.” Their writings marked the new epoch of poetry. In the late Tang, Li Shangyin and Du Mu brought Tang poetry to another pinnacle. They were good at using symbols and metaphors to describe subtle feelings. In order to distinguish from Li Po and Du Fu, they are called “Junior Li Du.”

Bai Juyi (772–846) was a famous realistic poet in the Tang dynasty. Bai always wrote a very profound verse with some simple words. It is said that whenever he finished a poem, he would read it to an old woman. Only if an illiterate villager could understand would he consider his

poems acceptable. Bai Juyi wrote almost 3,000 poems in his life. Most of his poems focused on the important social and political problems.

His long narrative poems *Pipa Song* and *Everlasting Regret* are his two best-known poems. *Pipa Song* describes a suffering song girl's life, which moved the author, an official in exile. He said, "Both of us are strangers here, both of us stranded, / Does it matter that we've just met, if our hearts understand?" This is one of the most famous sentences in Chinese literature. *Everlasting Regret* rewrote the love story of a Tang emperor, Xuanzong, and his favorite consort Yang Guifei. She was surprisingly beautiful. Emperor Xuanzong loved her so much that he neglected the affairs of state. She was blamed by people, and finally, in the rebellion of An Lushan, she was executed by officials in front of the army and the emperor.

The age was replete with literary anthologies, such as the *Collection of Literature* by Xiao Tong and *New Songs from the Jade Terrace* by Xu Ling. But *The Complete Collection of Tang Dynasty Poetry* was not published until 1707 in the Qing emperor Kangxi's regime. It is a 900-volume collection that contains 48,900 poems by more than 2,200 different authors. This is only a partial selection of Tang poetry; many poems could not be found after almost 1,000 years.

There are many poets in the Tang dynasty. Among the many poets of the Tang dynasty, Li Po and Du Fu are the most revered. They are considered the two leading poets in the history of Chinese literature. Though they were good friends, their writing styles were different. Li is seen as a Daoist hedonist, and Du is seen as a Confucian moralist. Li and Du separately represent the two main streams in Chinese literature: romanticism and realism. Both Li Po and Du Fu contributed to Chinese poetry by their talent and responsibility. A compliment by Han Yu, another famous Tang poet, has been always mentioned: "The works of Li and Du are there; their brilliant light will shine for ever."

Early Japanese Women Writers

Prior to Chinese contact Japan had no written language, but by the fifth century written Chinese was already becoming well established in Japan, its function being, in some ways, analogous to that of Latin in Europe. It was the language of official written discourse in the realms of politics and religion. Following the Chinese Confucian model, women were excluded from official participation in politics, and though a few did learn some Chinese, they were discouraged from demonstrating such knowledge.

By the ninth century an indigenous Japanese writing system called *kana* was developed. It used a relatively small number of simplified Chinese characters to represent sound alone, detached from meaning. Kana made it possible for the first time to write in pure Japanese vernacular rather than in Chinese. Kana writing was used by both sexes to record poetry, and the written exchange of poems was an important part of social discourse and courtship among the aristocracy. As the classical poetic tradition developed, many of the characteristics of the earliest poetry of women—the expression of personal, private emotions and a predominantly melancholy tone—came to dominate the formal Japanese poetry of both men and women.

Japanese women writers played a major role in creating their culture's classical, elite literary tradition. Although their significance lessened greatly in later centuries, around the turn of the second millennium CE women writers enjoyed

preeminence unparalleled in any other premodern literary tradition worldwide.

The first compendium of poetry in Japanese, the *Manyōshū* (*The Collection of Ten Thousand Leaves*), compiled in the mid-eighth century CE, includes significant verses by women from the earliest periods. *Genji Monogatari* (*The Tale of Genji*), often called the world's first novel, was the work of a woman. Women were viewed as the natural and appropriate creators of literature in the native Japanese vernacular. This position is clearly evidenced by an ironic contrast to Western literary tradition: the oldest extant example of Japanese narrative prose by an identifiable author is the *Tosa nikki* (*Tosa Diary*), a literary diary created by a man who wrote in the guise of a woman.

Several sociological factors help account for the prominence of women among the earliest Japanese authors. Mythological and historical evidence indicates the significant position of women in early periods of the culture. In *Kojiki* (*The Record of Ancient Matters*), a mythopoetic account of origins published in 712, the central deity is Amaterasu, the sun goddess, who is presented as the ancestor of the Japanese ruling house. The oldest foreign record of an encounter with people in the Japanese islands is a Chinese account describing a tribe led by a woman called Pimiko.

The overwhelming influence of political and religious systems and cultural values imported from the Asian mainland gradually brought a decline in the position of women, but one such cultural system, the Chinese system of writing and its subsequent adaptation in Japan, was crucial to the formation of literature in Japan and directly affected the role of women as writers.

Literary diaries were the most common form of classical women's writing. The earliest of these is *Kagerō nikki* (*The Gossamer Years*, translated by Edward Seidensticker). Written by a woman known to us only as "the mother of Michitsuna," it covers the years 954 to 974 and is a virtual autobiography recounting the author's unhappiness over her husband's diminished affection after his attentions shifted to a later secondary wife.

Another sort of diary is *Makura no sōshi* (*The Pillow Book*) by Sei Shōnagon, a woman in court service. Completed shortly after the year

WOMEN WRITERS IN LATE HEIAN JAPAN

Heian Japan (794–1192 CE) saw a proliferation of female authors who penned novels that are to this very day considered classics in Japanese literature. The reason for the number of women who wrote novels, diaries, and poetry, among other works, is mainly societal. During the Heian period, elite marriages consisted of visiting marriages in which the bride would remain with her natal family and the husband would visit periodically. This afforded these women much leisure time, and many used this time to write. In addition, women were forbidden to write in Chinese, the language used for all court and government transactions, making written Japanese known as a feminine language. This use of Japanese rather than Chinese made it more accessible to the lower classes and therefore more widespread. The most important pieces were written between 950 and 1050, and this movement of female writers is partially credited with the breaking with Chinese culture and the creation of what would become a uniquely Japanese culture.

—Monique Vallance

1000, it takes the form of a collection of notes, lists, and comments rather than a chronological diary or journal. The personal voice of Sei Shōnagon, witty and acerbic, contrasts strikingly with the self-pitying attitude of Michitsuna's mother. *Makura no sōshi* is still judged one of the greatest masterpieces of literary style in the Japanese language, and its random essay form became a mainstay of later literary writing by men.

Among all the writing by premodern Japanese, male or female, undisputed pride of place goes to *Genji Monogatari*. Like Sei Shōnagon but about a decade later, its author, Murasaki Shikibu, was also in service as a tutor to an imperial consort, apparently having achieved this position because of her established literary reputation. *Genji Monogatari* is a vast work of narrative fiction rather than a diary, more than 1,000 pages in English translation. Completed early in the eleventh century, it depicts an imaginary court of about a century earlier and centers around the amours of the idealized male hero, the prince Hikaru Genji, "Shining Genji." Its later darker

chapters shift, after the prince's death, to the amorous lives of two younger men, each a pale, partial reflection of Genji.

Though the work was read by both men and women, its primary audience was the women at court. It was written serially and circulated chapter by chapter, apparently read aloud and discussed among the women. For this audience *Genji Monogatari* must have been both diverting and soberingly instructive in its depiction of many aristocratic female characters of varied personality. As in women's literary diaries, more outward social and political concerns scarcely appear. The psychological intensity of women's passion, the negative power of jealousy, and the importance of personal taste and grace are its major concerns. Despite vast cultural differences, the book has an extraordinary feeling of modernity and accessibility.

The canon of classical Japanese literature includes about a half dozen other significant diaries and works of fiction by women. The last important flowering of the women's courtly literary tradition came some 300 years after *Genji* in the diary titled *Towazugatari* (*The Confessions of Lady Nijō*). Written by an imperial concubine, it describes both her years at court and her later life when she became an itinerant nun after falling out of favor. Not only is she writing in the tradition of earlier courtly women diarists, but she also shows instances in which court activities were modeled on scenes in *Genji Monogatari*.

The decline of the court, the rise of other genres of literature and drama, and the gradually declining social position of women in subsequent centuries shifted literary preeminence away from the brushes of women writers. Only in modern times has writing by Japanese women begun to regain significance.

Literature of India

India experienced a literary golden age during the first millennium CE. During that period, particularly in the Gupta Age, Indian writers produced works of enduring merit, works that influenced the literature of China, Southeast Asia, Persia, the Muslim world, and Europe and may have helped shape the oral literature of Madagascar and through that great island sub-Saharan Africa.

The compilation of the *Puranas* in written form was one of the great literary achievements of the Gupta Age (late third to early sixth centuries CE). The *Puranas* (*Tales of Ancient Times*), based largely on oral literature originally recited as early as several centuries BCE, were embellished and modified in written form during the early medieval age and perhaps after, but their written versions were substantially composed in the early part of this period. The *Puranas* are significant religious works not only for the Hindus but also for the Jains and Buddhists. The focus of the *Puranas* is on the mythical history mainly of northern India, but they are also of some value (when very judiciously used) as historical sources, especially in their genealogies of kings. The *Puranas* were written in Sanskrit but eventually became available in the vernacular languages.

Another important literary enterprise of early medieval India was the *Panchatantra*. Although the original version had been written earlier (some say as early as the third century BCE), the original texts had long been lost, and modifications and revisions of the project continued through the Gupta Age and after. The *Panchatantra*, consisting of fabulous tales of

animals that contained a moral lesson, sometimes thought to be useful for the ethical instruction for children, is also considered to have had significance as a political science text, giving Machiavellian instruction to aspiring rulers.

The tales in the *Panchatantra* involve such animals as the treacherous Dimna the Jackal and the pure of heart but rather simple Lion, king of the beasts. A clever monkey and cunning crows as well as donkeys and other animals also populate these stories. In the early medieval age, versions of the *Panchatantra* spread to neighboring peoples, especially to the Persians and from them to the Arabs and then the Europeans. In the *Shahnameh*, the great tenth-century Persian epic, Ferdowsi states that Shah Khosrau I in the late sixth century ordered the *Panchatantra* translated from Sanskrit to Persian. It has been said that the *Panchatantra* influenced much of the world's subsequent fabulist literature, including the ninth-century *Arabian Nights* and the nineteenth-century *Uncle Remus* tales.

The literary glory of northern India in its classical Gupta Age can be found in the works called *kavyas*, erudite works in prose and poetry written largely for the courts of the Guptas and other royal families. Kalidasa, who wrote perhaps during the reign of Chandragupta II (r. ca. 350-ca. 415), was one of the great writers of *kavyas* and was a playwright ranking with the fifth-century BCE Athenian playwrights Sophocles and Aristophanes and the sixteenth-century CE Englishman, Shakespeare.

The three plays of Kalidasa that have come down to us focus on the love of kings for beautiful girls or, in one case, a wood nymph. The most famous play that has been translated into English is *Abhijnanashakuntalam*, often called *Shakuntala*. In the play, a king falls in love with Shakuntala, the beautiful daughter of a forest sage, and looks forward to a happy marriage with her. Their idyll in the forest is cut short when the king is called back to court, leaving his pregnant bride to the wiles of a malignant magician, who puts her under the curse that the king will forget her unless she has the ring that he has given her. Unfortunately, Shakuntala loses the ring, and the king sends her away from his court. But the play has a happy ending when a fisherman finds the ring and brings it to the

king, who regains his memory of his forest love and goes back into the wilderness, where he finds her.

Kalidasa's poems include two epics, *Kumarasambhava* (*Birth of Kumar*), and *Raghuvamsha* (*Dynasty of Raghu*), but is also famous for his lyric poetry, including *Rtusamhara* (*Progress of the Seasons*) and *Meghaduta* (*Cloud Messenger*). *Meghaduta*, a poem of 111 stanzas, concerns a Himalayan mountain spirit whom the gods have exiled to the hot Deccan, in central India. The banished mountain spirit implores a passing cloud to carry a message back to his wife in the mountains. The message that the cloud takes to the mountains is a description of the wonders of the Indian countryside that the cloud passes over on its way to the mountain.

Although Kalidasa stands out as a composer of *kavyas*, he was but one of a galaxy of prose and poetry writers in the Gupta Age. One of the popular genres was the writing of plays, and many dilettante officers, including Emperor Harsha (r. 590-647), at the royal courts wrote plays as a social accomplishment.

A remarkable flowering of literary production in southern Indian languages, particularly in Tamil, occurred in the first millennium CE. The early centuries of the first millennium especially are regarded as a golden age for the development of Tamil literature. During this period, known as the Sangam Age, Tamil literature witnessed a great outpouring of works, including grammatical texts, epics, and a great deal of poetry.

Of the "Five Great Epics of Tamil Literature" (*Jivaka-chintamani*, *Siliappatikaram*, *Manimekalai*, *Kundalakesi*, and *Valayapathi*), *Siliappatikaram* (also spelled *Ciliappatikaram*) stands out as a Tamil classic. The authorship and dates of this epic are variously attributed. The subject of *Siliappatikaram* as well as of the other classic Tamil epics is the history of the Three Kingdoms in Tamil land, the kingdoms of the Pandyas, the Cheras, and the Cholas. *Siliappatikaram* waxes lyrical in its celebration of the geography and countryside of southern India. Jain and Buddhist authors composed these epics from the second to the tenth centuries CE.

Jains and Buddhists produced much of the Tamil literature during the period 300-600 CE,

but with the emergence of the bhakti movement, Hindu saints (63 Saivite Nayanmars and 12 Vaishnavite Alvars) composed a vast outpouring of devotional poetry, chants, and hymns. Appar was a famous Nayanmar who composed thousands of devotional hymns, 3,066 of which have survived. Other Nayanmars composed thousands more hymns, making the body of this work very great. The Vaishnavite Alvars were also prolific authors of devotional literature, especially the only female Alvar, Andal, and her stepfather Preiyalvar. Andal declared that she would marry no mortal man and pledged herself to the great god Vishnu. Vishnu was her symbolic lover, and her most beloved devotional song, *Vaaranam Aayiram* (*One Thousand Elephants*), describes in lyrical terms her wedding to Vishnu. It is still sung at weddings in Tamil Nadu.

None of the other major southern Indian languages has a literary tradition as old as that of Tamil. The literary tradition of the Kannada language is said to date from the middle of the first millennium CE, but the first surviving major work in Kannada is the *Kavirajamarga*, composed by Jains about 850 CE. The Telegu literary tradition started much more recently, perhaps not until the sixteenth century. Literature in Malayalam probably began to be composed after the twelfth century.

➤ “WHAT HAS INGELD TO DO WITH CHRIST?”— THE SURVIVAL OF SECULAR LITERATURE IN A CHRISTIAN TEXTUAL CULTURE

Alcuin (ca. 735–804), a scholar in Charlemagne’s court, demanded to know why monks in northern England were preserving the tales of the pagan past. His question “Quid Hinieldus cum Christo?” (What has Ingeld to do with Christ?) highlights the precarious position of secular literature in a monastic setting. Ingeld, a hero of the Scandinavian saga *Ynglingasaga*, represented heroic characters grounded in secular Germanic values of strength, loyalty, and generosity. Monastics were most likely preserving works featuring such secular characters not to undermine their faith but because these heroic tales were as much a part of their cultural identity as their religion.

—Todd Preston

The above includes some of the major literary traditions of early medieval India but is by no means exhaustive.

—Wilfred J. Bisson

European Secular Literature

Clarifying the term “secular literature” is essential prior to any discussion of the writings of the early Middle Ages. For our discussion, the term “secular” refers to works that are largely non-Christian in content or focus. Thus, the Old English poem *Beowulf* may be considered secular, even though the hero repeatedly praises and relies upon the Christian God. Similarly, although an argument may be made for considering everything from recipes to royal edicts as “literature,” we shall use this term to refer to larger works of philosophical, scientific, political, and historical prose as well as poetry.

While secular prose of the early Middle Ages assumed many forms, sometimes the remove from religious writing was very slight. Philosophical texts were most prone to this effect. The *Consolatio Philosophiae* (*Consolation of Philosophy*) of Boethius (ca. 480–525), for example, could be seen as a thinly veiled Christian text. Although the narrator of the *Consolatio* investigates humanity’s place in the larger workings of the cosmos, wrestling with questions of fate and free will, Christianity is not overtly invoked. However, this is more a function of the author’s reverence for his classical models than it is any refutation of Christian belief. In fact, the very nondogmatic nature of the text is what may account for its popularity through the centuries.

Scientific texts, like the philosophical ones, also owed a debt to the classical past. Martianus Capella’s (fifth-century CE Roman pagan writer) hugely influential *Satyricon* or *De Septim Dis-*

ciplinis (*On the Seven Disciplines*) laid the groundwork for scholarship throughout the Middle Ages. Separating the seven liberal arts into the *trivium* (logic, rhetoric, and grammar) and the *quadrivium* (astronomy, arithmetic, geometry, and music), Capella created a system for understanding the arts and sciences that found its way into courts and monasteries across Europe.

Political and historical texts of court and church during the period could intermingle fluidly. A text like the *Anglo-Saxon Chronicle*, for example, not only records the important events of a community but also provides political commentary. When the *Chronicle* reports Cynewulf's usurpation of Sigebert's throne in 755, the chronicler justifies Cynewulf's actions by pointing out Sigebert's "unryhtum dædum" (unrighteous deeds). Historical prose was likely to be very subjective in the medieval period.

Like secular prose, secular poetry of the early Middle Ages also took a wide variety of forms. In Old English, poems could range in form from the elegiac (i.e., lamentation poetry), like "The Wanderer," to the heroic, like *Beowulf*, to the gnomic (i.e., wisdom poetry), like the riddles of the *Exeter Book*. Verse forms could range from emulation of classical forms to native vernacular techniques. In content, the secular poems of the early Middle Ages largely focused on the myths and the real or imagined heroic deeds of the pagan past. *Beowulf* is the prime example of early medieval secular poetry. Although the Christian God does appear in the text, Germanic heroic values drive the characters in the poem. As much as *Beowulf* may call upon God for strength in battle, the narrator ultimately praises the hero as one not most devoted to God but as a man "most eager for fame."

European Christian Literature

For a largely illiterate region, a remarkable variety and amount of Christian literature was produced during the early medieval period. As the influence of the Christian church spread across Europe during the early Middle Ages, writings both in Latin and in the European vernaculars emerged from Greece to the British Isles.

A fitting origin for Christian literature in medieval Europe would be the Latin Vulgate Bible of St. Jerome (ca. 340–420). Editing the Old Latin Bible (the *Vetus Latina*) and translating anew from Hebrew and Greek exemplars, St. Jerome's more accessible Latin text was the basis for most theological and imaginative Christian literature for the medieval period.

Linguistically accessible Scripture may be of little use if it is ill applied. Therefore, early

➤ ADAPTING THE BIBLE TO SUIT ANGLO-SAXON CULTURE—MOSES, THE ANGLO-SAXON WARRIOR

One of the most interesting aspects of early medieval Christian writings is the way in which writers adapted Scripture to best suit their own culture. The Old English *Exodus* of the eighth century transforms the Old Testament text into heroic verse and casts Moses as "herges wisa" (the leader of the army) whose military victory over the Egyptians will ultimately ensure the Israelites' heavenly reward in "beorselas beorna" (the beer-hall of heaven). For the Anglo-Saxons, recasting Moses as a Germanic warrior-hero was a way of making the biblical story their own and ensuring the adoption of Christian texts and their values.

—Todd Preston

Christian writers wrote instructional handbooks to help the clergy spread the good word. Such an effort was the *Pastoral Care* of Pope St. Gregory I (“the Great”) (ca. 540–604). St. Gregory was a prolific author who contributed to shaping church doctrine and practice. *Pastoral Care* was well received and was reproduced throughout medieval Europe. Within the text, St. Gregory gives practical advice for the clergy’s care of its spiritual charges. Gregory outlines what kind of men should work for the Church, how to conduct oneself as a pastor, how to preach to various kinds of parishioners, and how to do all of this with humility. This influential work served as a handbook for clergy and as a meditation on all kinds of rule, both secular and sacred.

Once the right person was found for the job of pastor, he had to be able to deliver mass. This duty spawned a large body of liturgical writing. While the Scripture was the bedrock of Christian mass, interpretative sermons provided the means of bringing the Scripture’s message to the people. Abbot Aelfric of Eynsham (ca. 955–1010) was an acknowledged master of the form. Aelfric’s passion for reaching his audience was made plain in the preface to his *Catholic Homilies* (ca. 989). He wrote that his reason for writing in English rather than Latin was to “more readily reach the hearts of those who read or hear.” Liturgical texts, then, were not merely to announce the teachings of the Church but also to genuinely connect with the congregation.

Some of those early medieval Christians eagerly sought that connection to help explain the mechanics of their lives, giving rise to many philosophical treatises on religion. One of the early medieval era’s most influential meldings of philosophy and religion was the work of Boethius (ca. 480–524). A Roman citizen during the rule of King Theodoric the Ostrogoth (r. 493–526), Boethius wrote his *Consolation of Philosophy* (ca. 523–524) while imprisoned on spurious treason charges. Within his text, Boethius posits a discussion between his alter ego and Lady Philosophy. Following a model of Platonic discourse, Lady Philosophy brings Boethius to understand that everything happens for a divine greater good; all suffering is part of the divine plan. If liturgical texts like *Pastoral Care* helped to bridge the spiritual gap between clergy and

parishioner, philosophical texts such as *Consolation* helped to provide a rational understanding of the mechanics of providence.

Spiritual and intellectual understanding of Christian teachings inspired a large number of imaginative works in the early Middle Ages. Anglo-Saxon poets could turn the biblical Exodus into a heroic poem in the eighth century or have a gospel book speak the riddle of its identity in the tenth century. Christian teachings had passed from the precincts of the churches and cloisters into the popular imagination. The impact of Christianity on the literature of the early Middle Ages is profound and, ultimately, inestimable. What the religion fostered was a diverse, profuse, and meaningful literary heritage.

Arabic Literature

Arabic literature has a rich and wide-ranging history. In its Classical Period (sixth to twelfth centuries CE), it developed in diverse artistic directions. In the cultural melting pot of the early Islamic world, indigenous Arabian literary ideas and forms blended with middle Persian, Greek, and Indian traditions to produce a colorful literature in the Arabic language. Poetic genres such as tribal odes, brigand poetry, ele-

giac laments, love lyrics, court panegyrics, scathing satires, and mystical verses emerged side by side with prose genres such as scripture, orations, epistles, fables, mirrors for princes, and popular tales, all with their own intriguing features. Centuries later, these texts still provide us with a firsthand view of the culture and thought of the classical Arabic-speaking world.

Arabic was a distinct language by the third century CE. In the pre-Islamic period of the sixth century CE, poetry and oratory had already emerged in the Arabian Peninsula as fully developed art forms. From this period some short poems, primarily elegies by women, and a larger collection of odes by men have survived. The latter form typically included the following tripartite structure: first a love prelude, with the poet weeping over the deserted encampment of the departed beloved, followed by a journey through the wilderness with descriptions of the poet's mount, camel or horse, and of desert landscapes and animals, and finally a section of tribal praise or self-praise, focusing on the twin heroic motifs of generosity and courage. These odes, on average between 60 and 130 verses in length, were set in monorhyme and monometer verse. Their composers used a standard nondialect form of Arabic that was used for intertribal communication and for all "high" literature. Among these odes, the most famous are the seven called *mu'allaqat*, and of them, Imru' al-Qays's *mu'allaqat* is perhaps the best-known poem in all of Arabic literature.

Poetry was considered the register of the Arabs, a record of their great deeds and culture, even their conception of the meaning of life and death. It had a ritual and mythic function, and poets, in the pre-Islamic period, were believed to possess semidivine, shamanistic powers.

Although oratory was the major Arabic prose genre during pre-Islamic times, relatively few examples of this form have survived. Extant pieces consist of rhymed pronouncements by soothsayers, pious sermons about the inevitability of death by pagans and Christians, and political speeches by tribal leaders during periods of intertribal hostility.

With the advent of Islam in the early seventh century CE came its Holy Book, the Quran. Muslims believe that the Quran was the word of God, containing knowledge of all things revealed to

his prophet Muhammad through the archangel Gabriel. The Quran had no literary precedent, being neither poetry nor prose. Its miraculous nature was attributed in part to its use of language. The Quran had an enormous influence on subsequent Arabic literature. The desire for Muslims to understand the linguistic and idiomatic context of the Quran, in addition to their wish for tribal valorization, motivated many Muslims to preserve earlier poetic materials.

In this period oratory continued to exist as a major prose genre. 'Ali b. Abi Talib, an important religious and political personage of early Islam, composed orations that delineated the Arabic path of eloquence. Most of the literature produced up until the mid-eighth century was oral. Scholars memorized and orally transmitted these works to subsequent generations. In the late eighth and early ninth centuries scholars such as Sukkari, Mufaddal, and Asma'i began physically copying these works.

The Arabic language spread to Persia, Syria, Iraq, and Egypt in the mid-seventh century with the Muslim conquests of these lands and, to a large degree, replaced the local languages. The emerging Islamic empire adopted the bureaucratic forms of the Sassanian and Byzantine empires it had conquered. Although written Arabic prose had existed since early Islamic times in the form of treaties and brief epistles, as the empire expanded Islamic leaders found it increasingly necessary to disseminate policy edicts more widely. This gave rise to a chancery that produced polished policy documents.

In 697, when the Umayyad caliph 'Abd al-Malik required the use of Arabic in the imperial chancery, it became the seat of Arabic literary prose. Most chancery officials were Persian or Greek; therefore, the first written Arabic literary prose developed under the impetus of these groups' respective writings on statecraft while being simultaneously influenced in style and theme by the indigenous Arabic oratorical tradition. In comparison to oratory, this epistolary style emphasized longer syntactically parallel constructions. 'Abd al-Hamid al-Katib was this form's most celebrated proponent. The vast majority of writers emulated his style, although a century later the emphasis shifted again to rhyming prose.

Part of a text by Severus, Christian Patriarch of Antioch, about 800 CE. By this time, the majority of the literature in the West, whether by Muslim or Christian writers, was in Arabic. (The British Library)

Umayyad poetry brought in new dimensions with the introduction of vituperative poetic duels. Farazdaq, Jarir, and Akhtal are famous for their bawdy satires. Furthermore, two new schools of love poetry emerged. ‘Umar b. Abi Rabi’a represents the Hijazi style, with flippant dialogue and a coquettish beloved, and two poets from the tribe of ‘Udhra, Jamil and Majnun, represent the ‘Udhri style, with expressions of grieving laments and unfulfilled, undying love. Poets of the Umayyad period, such as Farazdaq and Kumayt, also composed religio-political poetry in praise of the family of the prophet.

The subsequent Abbasid period was one of great literary efflorescence. In the early ninth century, the caliph Ma’mun founded an institute in Baghdad, called the House of Wisdom (Bayt al-Hikma). Under the leadership of a Nestorian Christian, Hunayn b. Ishaq, its scholars translated works of Greek philosophy, via Syriac, into Arabic. This translation movement produced a rationalist trend in Arabic literature that influenced many contemporary writers. Abbasid society’s appreciation of literature, its opulent multiethnic courts that encouraged literary production, and its openness to new ideas and cultures gave rise to creative innovations in both

prose and poetry. The geographical compass of Arabic literature also expanded. In addition to the Arabian Peninsula, Syria, and Iraq, Arabic literary production was now coming out of Egypt, Persia, and central Asia.

Fiction, in the Arabic mind, had initially been considered “untruthful” and thus morally reprehensible. This negative perception changed gradually but never really disappeared until modern times. Early Arabic authors of fiction adopted the form of historical writing. This form consisted of real or made-up anecdotes, each framed by an oral chain of transmission (*isnad*). These early works also exemplify a genre of prose called *adab*, literally meaning “good manners” but also “literary culture.”

Ibn al-Muqaffa, a Persian scribe, produced the first Arabic work of fiction. His “mirror for princes” fable *Kalila and Dimna* was an Arabic reworking of a Persian book that itself was a translation of the ancient Sanskrit text *Panchatantra*. A prose writer from Hamadan nicknamed Badi’ al-Zaman, or “Marvel of the Age,” produced an original picaresque protonovel titled *Standings*, with an eloquent rogue as its hero. Jahiz, an essayist from Basra of East African lineage, wrote approximately 200 *adab* treatises on a vast range of topics, including animals, misers, politics, geography, and literary theory. These authors’ works were immensely influential in shaping the course of Arabic prose.

Poetry also expanded in new directions. A multiplicity of new and reworked genres emerged in Abbasid lands, such as homoerotic, wine, Arab-bashing, and ascetic poetry. In Fatimid Egypt, a new genre of religious mission poetry developed. This was also the age of the professional panegyrist (a poet who wrote praise for an individual) who was often a salaried employee of the state. And it was the age of stylistic innovation, with the introduction of far-fetched metaphors and excessive wordplay. Abu Tammam was a state panegyrist who famously praised the Abbasids’ military victories over the Byzantines. He is considered the principal proponent of the “artificial” *badi’* school. Mutanabbi was another celebrated panegyrist who lived in the tenth century. His descriptions of battles and horses as well as his gnomic pronouncements

on death are memorized and quoted by Arabic-speaking peoples to this day.

By the mid-ninth century, literary culture was widely accessible to the masses. Many famous litterateurs rose from humble socioeconomic beginnings to enjoy some of the best education of the day. Public lectures were commonly held in mosques on religious and secular topics, as were public debates. Baghdad boasted an entire market devoted to booksellers, which consisted of approximately 100 shops. The public libraries of Baghdad and Cairo contained tens of thousands of books (some reports go up to 200,000). Library budgets routinely included expenses for paper and ink in order to allow individuals to make their own copies. Arabic literature, in this period, transitioned from a primarily oral to a primarily written mode as paper-making techniques from China reached the Islamic world.

Alongside “high” literature composed in pure, classical Arabic, a tradition of popular tales had existed since at least the ninth century. These tales were in “middle” Arabic, a mixture of colloquial dialects and standard classical. Professional storytellers narrated fantasy tales sprinkled with myth, folktales, history, poetry, and Scripture, Arabic tales that had echoes from Persian, Turkish, Greek, and Indian cultures. The famed collection *Thousand and One Nights* (also known as *Arabian Nights*) took its Shahrazad frame story from an old Persian tale and used it to encompass all aspects of fascinating stories. It evolved over many centuries and was eventually written down in several versions. The storytellers also narrated epic story cycles (*sira*) of valiant heroes, such as the pre-Islamic ‘Antar, the warriors of the migratory tribe of the Banu Hilal, the warrior-princess Dhat al-Himma, and later of the Mamluk prince Baybars.

In the Far West, Arabs had entered Europe through North Africa as conquerors in the early eighth century. The Umayyad caliphate of Andalusia produced a good deal of literary material. Most of the important literary figures of Arab Spain are, however, from the eleventh, twelfth, and thirteenth centuries and thus outside the scope of this article. Non-Arabic speaking Muslims in South, Far East, and central Asia also

➤ “PRECIOUS GEMS”

“Halt, O companions both! Let us weep at the remembrance of a beloved and a campsite by the winding of the dunes, between Dakhul and Hawmal

and Tudih and Miqrat, whose traces have not been effaced from the weaving through of the North and South winds.

You see the droppings of white antelope in its open spaces and lowlands, like balls of peppercorn.

As though I—on the day they loaded their camels near the tribe’s acacia trees—were peeling bitter colocynth-onions.”

(Translated from Arabic by Tahera Qutbuddin)

Thus opens Imru al-Qays al-Kindi’s famous muallaqa ode, some of the best-known lines of Arabic literature. Sixth-century CE Dakhul, Hawmal, Tudih, and Miqrat are the names of ancient tribal camping sites in Arabia.

Poetry was the main art form of the Arabs in pre-Islamic times, and the best odes were reportedly selected by an intertribal council at the annual cultural fair of Ukaz to be written in letters of gold and hung on the holy shrine of the Kaaba in Mecca.

The poet gave the ode no real title. It is known as “the muallaqa of Imru al-Qays.” The etymology of the word “muallaqa” is disputed. The meaning might be “precious gems.” Or it could mean “the hung one” (on the walls of the Kaaba).

—Tahera Qutbuddin

produced a large amount of religious Arabic literature from the eighth century onward, but modern scholarship currently lacks a detailed study on this topic.

In conclusion, classical Arabic literature developed from an oral tribal-inspired set of odes and orations into a largely urban writing culture that included religious tracts, historical works, geographical studies, and grammatical texts and, in belles-lettres, incorporated new genres of poetry as well as literary epistles and fictional prose.

—Tahera Qutbuddin

Persian Literature

Persian is the ancient language from the region of Fars in modern-day Iran. As the language spread northeast into central Asia during the first millennium, Persian solidified its position as the cultural language in Greater Iran. This region underwent massive change in the mid-seventh century when the population rapidly converted from Zoroastrian to Islam, and the Persian language adapted to the introduction of Arabic vocabulary and script, resulting in the transformation of Pahlavi, or Middle Persian, into New Persian. These two major changes sig-

nificantly influenced Persian literature by incorporating new vocabulary, introducing innovative literary styles, and shifting themes within poetry and prose. Despite a lull immediately proceeding the Islamic Conquest, Persian literature experienced a revival during the reign of the Samanids (ca. 850–999 CE), culminating in the composition of the great Persian epic the *Shahnama*, written by Firdawsi (935–1020 CE). Firdawsi's work is the quintessential Persian chronicle, and Persian children continue to study it for its patriotic and nationalistic value.

Early Persian literature emerged from the versed *Gathas*, or psalms, of the Zoroastrian sacred book the *Avesta* (written ca. 1000 BCE); lyrical hymns better enabled priests to remember the words of recitation. Since only a small portion of the reported 20-volume text remains, the *Avesta* is not generally regarded for its literary significance. Zoroastrian influence decreased following Alexander the Great's conquest of Greater Iran in 331 BCE, and there was a subsequent decline of religious, secular, and literary efforts.

It was not until the Sassanian dynasty (224–651 CE) and the ensuing surge of Persian identity that there developed significant secular literature as well as literary professionals such as court poets and historians. The role of poets was often combined with that of court singers. Despite very few remaining Sassanian writings, information from later sources identified a few poets including Barbad and Nakisa as well as several kings. Popular subjects of poetry included love, wisdom, and wine, and poetry was even used to deliver bad news, such as when a beloved horse died and the poet-singer Barbad was selected to inform the king, which he did in a versed tale. During this time, the writing of dynastic histories became popular, as they could further solidify the power of monarchs. Such panegyrics, or highly praising verses, were the most common examples of prose, along with scholarly topics such as philosophy and sciences. There are very few remaining examples of fiction and drama; such works of prose resemble poetry, as they contain elements of rhymes and rhythms.

The seminal division in Persian literature is the 651 Muslim Arab conquest of central Asia, which introduced new literary topics. Persian

► THE SHAHNAMA

The *Shahnama* (*Book of Kings*) is the only Persian epic of Iran's glories and people. It begins at creation and continues through the Sassanian defeat by the expanding Muslim Arab empire. The *Shahnama* is divided into three sections: the mythic, the legendary, and the historic. The mythic section focuses on the creation of the world and the development of society. A prince named Rustam is the central figure of the legendary section. In order to save his king, Rustam faces seven trials, including slaying a dragon, killing a witch, and defeating a demon. This hero also faces tragedy when, during battle, he inadvertently kills his son, Sohrab. The legendary section also features several well-known romances, such as that of Zal and Rudaba. The final section is factual and covers the centuries between Alexander the Great in 331 BCE and the Islamic conquest in 651 CE.

—J. Tia Wheeler

literature was ebbing, and it was not until the Abbasid power in Baghdad solidified and the concurrent rising Eastern influence that Persian literary efforts increased. During that time, the hub of Persian literature was the city of Merv, an ancient Zoroastrian center. Abbas of Merv is nominally identified as the first bard of the New Persian language. When the Abbasid caliph Mamun came to Merv in 809, Abbas was selected to author a panegyric that he chose to compose in Persian instead of the customary Arabic. Despite this effort by Abbas to advance his native language, many Persian authors wrote in Arabic, as that was the official court language of the Abbasid rulers.

When Abbasid authority declined and the Samanids of Persia came to power in the mid-ninth century, Persian literature witnessed a revival that reflected the contemporary political changes. Prominent were historical writings focusing on the pre-Islamic era by recalling Persia's heritage, and once again panegyric epics served as propaganda for monarchs who encouraged such writing through royal patronage. The writing style became progressively more refined to make the words pleasing to hear when recited to the king and royal court. Despite Islamic bans on alcohol, bacchanalian poetry continued to thrive. A new popular topic was self-elegies in which the writer would often comically lament his lost youth. One poet, who composed a humorous quatrain on vanity, in particular the need to dye graying hair, was Rudaki (ca. 880-ca. 954 CE). The blind author was a prolific writer with more than 1 million verses attributed to him, yet less than 100 remain today. Of those lost, the best known was his poetic Persian translation of the animal fables, *Khalila and Dimna*.

Another famed Persian writer, Daqiqi (ca. 940-ca. 976 CE), began composing a great Persian epic before his murder by an esteemed slave. Like his other writings, it revealed a strong Zoroastrian identity and focused on wine and women. His approximately 1,000 verses of the epic were not lost, as they were soon incorporated by Firdawsi into his work that was to become the *Shahnama*. Firdawsi, who like Daqiqi was from the city of Tus, claimed to have seen the dead poet in a dream in which Firdawsi was charged by Daqiqi to continue writing the epic.

Firdawsi spent more than 30 years composing the *Shahnama*, and in its unabridged form it has 60,000 couplets and is approximately ten volumes in length. It continues to be regarded as the greatest literary example of the Persian language, largely because of Firdawsi's deliberate selection of Persian-origin words in avoidance of the Arabic-diluted New Persian. Thanks to its prominence as a national epic, manuscripts of the *Shahnama* have been commissioned by most Persian-speaking monarchs during the past millennium, and many of these manuscripts include magnificent illustrations that exemplify Persian painting.

Byzantine Literature

Byzantine literature developed from pagan classical genres that were adapted to Christian needs along with new and explicitly Christian literary forms. In late antiquity (ca. 300–500) literature in Latin, Syriac, and other languages flourished in the eastern Roman empire, but after the mid-seventh century it was written in Greek. Formal literature was modeled after the language of classical Athens, imitating styles and themes of the Hellenistic and Second Sophistic period (second century CE). It was written by and for the educated literary elite who also read and preserved ancient works. Late ancient literature became increasingly divergent from spoken language and has been criticized as artificial and divorced from reality, but current scholars argue

that Byzantine writers could be innovative and creative in their use of classical models. Most literary works were declaimed, sung, or performed, and the messages in letters were presented orally, so current translated texts cannot convey their full impact on their audience.

Byzantine literary genres were defined in a complex accommodation between Christianity and pagan literature and between Greek, Latin, Syriac, and other Eastern languages. Classical pagan traditions in history, rhetoric, letter writing, and poetry (especially epigrams) in both Latin and Greek thrived during this period. Histories focused on rulers and military and diplomatic events, presenting causation, morals, and character through the insertion of speeches on the models of the ancient historians Thucydides, Herodotus, and Tacitus. Notable works were the *Res Gestae* of Ammianus Marcellinus, a Greek soldier who wrote in Latin, and the sixth-century *History of the Wars of Justinian* by Procopius of Caesarea. Classicizing histories, many surviving only in fragments, continued throughout late antiquity and were revived in later centuries. As the empire became Christian, alternative historical models were developed. Eusebius, bishop of Caesarea, created genres of salvation history that were followed throughout the medieval world, building on translations into Latin, Armenian, Syriac, and Coptic. His *Ecclesiastical History* traced the church from its origins to Constantine using documentary evidence, and his *Chronicle* systematized chronologies from the creation of the world to the time of writing, tracking events that foretold God's plan for salvation through annual entries in simple language and style.

In the fourth century, Christian leaders educated in the classical rhetorical tradition appropriated it for orations, sermons, panegyrics, and theology, combining classical genres with biblical references and Christian argument. The Greek Orthodox Church fathers Basil of Caesarea, Gregory Nazianzus, Gregory of Nyssa, and John Chrysostom, like their counterparts Ambrose and Jerome in the Latin Catholic west, created models that were copied, translated, and imitated throughout later Church history. In late antiquity, bishops delivered sermons in large-scale public events that attracted masses and were copied by stenographers. Gregory Nazian-

zus's sermons included funeral orations for family members and friends and homilies for Christian festivals. The sermons of John Chrysostom ("Golden mouth") interpreted biblical texts and stressed morality and social justice and are among the most widely copied Byzantine manuscripts. Christian emperors were celebrated in panegyrics as their pagan predecessors had been, following Eusebius's *Life of Constantine*. Intellectuals circulated letters that were formal compositions of argument, persuasion, or consolation in Christian as well as pagan circles, and letter collections survive from many periods of Byzantine history. As rhetorical showpieces, they were meant for dissemination, and private messages were generally conveyed orally.

Hagiography—works describing the lives and miracles of holy men and women—was among the most popular and distinctive literature of late antiquity. Developed from classical biography, the lives of philosophers, and romantic novels, saints' lives and ascetic tales traced the spiritual heroism of desert-dwelling hermits, monks, and bishops, of so-called holy fools, and even stylites who lived on high pillars. Late ancient hagiography also included lives of women saints, from Gregory of Nyssa's praise of the domestic holiness of his sister Macrina to tales of women who disguised themselves as men to live as ascetics. Late ancient hagiography was identified by its subject matter rather than its literary form, and holy men and women were memorialized in forms that ranged from extensive letters to collections of monastic tales and of the miracles performed at healing cult centers and from philosophical biographies in rhetorical Greek to lives of rural saints written in rustic language. All reflected a new emphasis in Christianity on the need for human figures who could provide intercession, cures, and direct communication with God. A new hymn form, the *kontakion*, developed from Syriac tradition as a dramatic sermon in verse and was incorporated into the liturgy. The most famous of these, the *Akathistos* hymn, is still sung today.

During the Byzantine Dark Age of the late seventh and eighth centuries, reading and literature declined among the elites, and much of what was written was destroyed in the Iconoclast Controversies. Chronicles and theological

and polemical writings can be reconstructed from their incorporation into later works such as the early-ninth-century *Chronographia* of Theophanes. Saints' lives of monks and bishops who opposed iconoclasm still exist in large numbers, almost all written in the ninth century or later, at the end of the controversy.

The ninth-century revival of education and scholarship and development of minuscule script, which made manuscripts more available, led to a revival of literature in the tenth century characterized by encyclopedism and the use of classical forms and language. Although scholarly circles existed in the capital from the early ninth century, the patronage of Constantine VII Porphyrogenitus (945–959) of literature was especially important. He commissioned histories of his dynasty that were continued and imitated later, centering on the reigns of the emperors, and compiled a historical encyclopedia of materials essential for governing, drawing on classical and early Byzantine texts in the imperial library. Hagiographical texts were rewritten in a uniform, more rhetorical style and organized to correspond to the liturgical year in the *Menologion* of Symeon the Metaphrast (ca. 1000), but the number of new saints lives declined. To this era also belongs the most important collection of classical and Byzantine epigrams, the *Palatine Anthology*. Literary epistolography (the study of writing letters) flourished in the tenth century, and collections of the letters of leading secular and religious figures survive. Like their

classical models, Byzantine letters were rhetorical gifts, demonstrating the author's ability for elegant, often obscure expression on topics such as friendship, consolation, and blame. Modern scholars have dismissed them as obscurantist rhetoric, but current study of the nature of letters and letter collections underlines their importance for understanding Byzantine emotions and literary culture.

If Byzantine literature was created from the interaction of classical and Christian needs in late antiquity, its revival in the ninth and tenth centuries made it the hallmark of the growing literary culture shared by Byzantium's growing secular and religious intellectual elite. The classical literature revived, and new works created in this period formed the basis for an expanding literary culture in later centuries. Translated into Slavonic, it also created the culture of the newly converted orthodox world of the Byzantine Commonwealth.

■ Introduction: Art and Architecture

In this topic, we discuss visual art and architecture: architecture, sculpture, some material culture, and painting. Aesthetic reasons motivated creation of this art, but most of it also served political and/or religious purposes.

Religious art in the early medieval age was intended to be didactic, that is, to make a statement about the truth, the glory, and the power of the religion that was the subject of the art. Its purpose was to educate, to advertise, to impress the viewer with the beauty and force of the reli-

gion. Religious art includes monumental architecture and sculpture, such as the great Buddhist temple Borobudur, the Mesoamerican and Andean pyramid temples, the Ajanta and Elora cave temples in India, and churches, mosques, and other places of worship and the like as well as smaller objects, such as holy statues, paintings, and other works intended to convey a visual message.

Religious art, especially monumental art, often also carried a political message. Usually a

ruler who was interested in legitimizing his rule or demonstrating the power of his regime undertook the vast scale of constructing a large temple, church, or mosque. For example, when Byzantine emperor Justinian built Hagia Sophia on the site of a previous church, he emphasized his power by building larger and more magnificently than his predecessors. Umayyad caliph al-Walid, to demonstrate the superiority of Islam, ordered the construction of the Grand Mosque of Damascus, which was to be built on the site of a demolished Christian church and on a more lavish scale than Constantinople's Hagia Sophia.

The Mahayana Buddhists showed their devotion and gained religious merit by commissioning the construction of huge Buddha sculptures, such as those at Bamiyan, Afghanistan, or at Longmen, China. The representation of Buddha in visual art was an innovation by the Mahayana in Buddhist practice. Originally, Buddhists had frowned on any pictorial or sculpted representation of the Buddha. But in the early centuries CE, Mahayana Buddhists began to construct monumental art depicting the Buddha and other religious subjects on a prodigious scale in India, central Asia, China, Korea, Japan, and Southeast Asia.

In India, the monumental art of the Jains and the Hindus rivaled that of the Buddhists. In the sixth and seventh centuries, these three religions competed in constructing elaborate cave temples, their interiors covered with religious paintings in central India at Elora and Ajanta. By the seventh century and after, devotees of the Hindu deities Vishnu and Shiva built elaborate temples, covered with exquisite religious sculptures, for the glory of their gods. In southern India, kings constructed temple cities as pilgrim centers in which religious art became important not only for political purposes but also to stimulate the pilgrim economy.

Christians originally appropriated pagan temples as their sites of worship. Often they would demolish the pagan temple, building something specifically Christian, but sometimes also, as at the Roman Pantheon, Christians would use the original structure with little except cosmetic modification. That the early Christians were very conscious of the power of religious art is shown by the Egyptian Christians defacing the inscriptions and pictorial work on ancient pagan

Egyptian temples. Christians themselves soon developed a religious artistic tradition in sculpture as well as in painting. In a largely illiterate era, religious paintings (icons) were used to propagate the teachings of the church. In the eighth and ninth centuries, many Christians, perhaps influenced by Muslims, objected to the visual representation of certain religious subjects, causing a very intense political and religious struggle, the Iconoclast Controversy that convulsed the Byzantine empire in the eighth and ninth centuries.

Muslims were forbidden to employ visual representation (graven images) of living creatures in their religious art. Instead, Islamic religious art featured elaborate calligraphic representation of Quranic verses, floral designs, or abstract symbols.

—Wilfred J. Bisson

Persian Architecture and Hunting Gardens during the Sassanian Dynasty

The Sassanian dynasty began with Ardeshir I's conquest of the Parthian capital, Ctesiphon, in 226 CE. The Sassanian kings, in an attempt to revive the glories of the ancient Achaemenid empire, announced Zoroastrianism as the state religion and erected several Zoroastrian temples as well as palaces in different parts of their territory. Some famous Sassanian palaces are *Tagh-i Kasra*, Bishapur, Firuzabad, Imarat-i Khusro, and Haus Kuri.

In their attempt to revive Achaemenid architecture, the Sassanians actually developed new architectural styles and construction methods. In Sassanian architecture new vaulting techniques were used in erecting huge arches and domes in buildings such as *Tagh-i-Kasra* and *Firuzabad* palaces. A significant Sassanian contribution to construction methods was solving the problem of the propagation of a circular dome on a square building by using squinches. This system was later widely used in Islamic and European architecture. Mud and brick were used as the main material in constructing buildings, and in terms of decoration molded or carved stucco decorations in massive walls were applied. Roman and Greek influence can be seen in the grid plan and mosaic decorations of the

➤ SASSANIAN GRANDEUR—CTESIPHON

The grandeur of the Sassanian dynasty is well illustrated in the surviving palaces such as Tagh-i-Kasra in the capital city of Ctesiphon, which is located south of Baghdad in Iraq. This city, which was founded by Parthians, was later developed by Sassanians. Ardashir I (r. 224–241 CE) selected it as his capital. This Sassanian city with its circular site plan was later developed by Khosru I Anushirvan, who added and built a new suburb to accommodate refugees from Antioch in 540 CE. Taq-i-Kisra, Khosru's palace, is probably the most famous monument at Ctesiphon. Using the barrel-vaulted *iwan* inherited from the Parthian period, Taq-i-Kasra is famous for the huge size of the arch in the great vaulted hall, which is credited to the reign of Shapur I (r. 241–272). The principal feature of this entirely brick structure is its open arched *iwan*, which has a facade decorated with blind architectural features, arranged in six registers of engaged columns and niches. Its huge size (more than 80

Photograph from about 1930 shows the remains of the facade and open audience hall of the Sassanid Palace of Tagh-i-Kasra in Ctesiphon, Iraq. (Library of Congress)

feet in width and 118 feet in height) has made it one of the masterpieces of Persian architecture.

—Mohammad Gharipour

Anahita temple in Bishapur and in wall paintings in Kuh-i Khwaja in Sistan.

Respect for Anahita, the great goddess worshipped during the Achaemenid dynasty, motivated Sassanian kings such as Ardashir I and Shapur II to build their palaces near natural hot springs (which are rich in plants and water) like Firuzabad in Fars and Takht-I Soleiman in Azerbaijan. Sassanian kings engraved reliefs in several parts of their territory such as Naghsh-I Rostam, Tagh-I Bostan, and Bishapur to show important events such as their victories over Romans and the enthroning of kings. During this time several Christian churches were erected in Persian cities such as Hira, Ctesiphon, and Rahalica.

Since the Sassanian kings were so interested in hunting, they revived the Achaemenid concept of hunting gardens, such as those in Firuzabad, Sarwistan, Ghasr-I Shirin, Takht-I Soleiman, and Hawsh Kuri, rather than concentrating on ornamental palace courtyards. In the plans of most Sassanian palaces, pavilions were located at the intersection of four avenues in the center of an enclosed garden, which contained rare animals. Archaeologists have found traces of the earliest Sassanian gardens in Ray (in modern

Tehran), Firuzkuh, and Ghal-I Dokhtar. In Ray, remains of a great walled enclosure known as Ghal-i Ghabr are believed to be the remains of a Sassanian garden for the royal hunt. The remains of another large garden in Firuzkuh reveal the existence of a Sassanian *paradeisos* (hunting garden). In the fire temple in Ghal-I Dokhtar, built by Ardeshir I, archaeologists could find the evidence of a pool and garden in the courtyard. Ardeshir II (379–383 CE) ordered the design of another hunting garden in Taq-i-Bustan probably for hunting wild boar and deer. Shapur II's sanctuary in Takht-I Soleyman, dedicated to the water goddess Anahita, was probably a hunting garden encircling Anahita's fountain. Another famous Sassanian hunting garden was located in Khusrau II Parviz's (591–628 CE) palace, Imarat-i Khusru, at Ghasr-i Shirin. This palace stood on a high terrace in the center of a great garden encompassed by a wall. A great pool is located between the palace and the monumental entrance portal on the east side of the complex. At the same level as the garden, a vaulted passageway ran around three sides of the eastern half of the terrace. Khusrau II Parviz had a smaller palace at Hawsh Kuri that was set in a rural location on a

lifted terrace with a vaulted hall to view the garden. The palace of Hawsh Kuri included an avenue that ran from the eastern side of the palace to a pavilion and from the northeast corner of the palace to the monumental entrance portal of another enclosed garden.

Funerary Architecture in Iran, 651–1157 CE

The development of funerary architecture has always been dependent on the concept of death in different cultures and ages. Zoroastrianism, Iran's official religion before Islam, prohibited burying corpses. Consequently, Persians did not build luxury tombs in the Sassanian era. After the Muslim invasion of Iran, many people, voluntarily or forcibly, converted to Islam. According to this new religion, humans should leave this world as they were born. So in the early Islamic years, people avoided a whole range of mourning practices, including wailing and the sprinkling of ashes or dust on the body. In terms of architecture, the grave was supposed to be level with the ground, and no structure of any kind could be there to mark it. During the Abbasid dynasty (r. 750–1285 CE), an elaborate burial

➤ GONBAD-I QABUS TOMB TOWER

Gonbad-i Qabus, erected in 1006–1007, was the first Persian tomb tower. It was built in the city of Gonbad in the southern coast of the Caspian Sea, a region of Zoroastrian Persians who resisted the Abbasid caliphs for several centuries. This tomb tower was built to honor Qabus, a famous scholar king and outstanding author in Persian literature. Since Zoroastrianism prohibited underground burials, they built a brick tomb tower 180 feet (55 meters) high in which the mummified corpse was suspended from the roof in a glass coffin. Constructing tomb towers became fashionable after the eleventh century in northern Iran, where tomb towers also functioned as city landmarks.

—*Mohammad Gharipour*

Tower tomb of Prince Gonbad-i Qabus, erected in 1006–1007, Mazandaran, Iran. (Alinari/Art Resource, NY)

practice gradually emerged. The corpses of some of the Abbasid caliphs were covered in richly worked expensive silk clothes (instead of plain white cotton ones) and were put in elaborately carved coffins made of expensive wood. Under the influence of Christian Roman culture, which persisted in some areas of the Abbasid empire such as Syria, mausoleums became fashionable. Probably the earliest Islamic mausoleum was erected in Samarra in the ninth century. The octagonal shape of this monumental mausoleum, called Qubbat al-Sulaibia, reminds us of the architecture of Roman mausoleums.

Under the influence of funerary culture of Turkish tribes, Samanid (r. 819–999) and Ghaznavid (r. 821–1055) kings who ruled Iran showed an interest in erecting royal mausoleums. The most famous mausoleums and tomb towers in this era are the mausoleums of Amir Samanid, Sultan Qabus, and Alp Arslan. At that time, the construction of mausoleums was limited to the boundaries of the Samanid and Ghaznavid empires. They were not built in southern Iran. The outstanding mausoleum of Amir Samanid was erected in 907 in Bukhara, which was the capital of the Samanids. In this mausoleum, four small domes are placed on drums around a central dome, while the facade of this domed square mausoleum is richly decorated with brick.

In the eleventh century several mausoleums and tomb towers such as Samiran, Sangbast, Chehel Dokhtar, Khargan, Pir-e Alamdar, and Gonbad-e Ali were erected in different parts of Iran. The Samiran tomb tower in the mountainous regions of northern Iran, one of the earliest tomb towers, has a polygonal plan similar to the plan of Qubbat al-Sulaibia Mausoleum in Samarra. Pir-e Alamdar Mausoleum (ca. 1026–1027) in Damghan was erected near a mosque to honor a Sufi mystic in Iran. After the construction of this mausoleum, the erection of religious mausoleums as royal tombs became the style in Persian architecture. One of the last royal mausoleums, Sangbast, is a domed square building, dedicated to Alp Arslan, a famous Ghaznavid king who died in 1028. A dome through a deep zone of transition surmounts the square chamber of this building. The last Samanid mausoleum is Gunbad-e Ali (ca. 1056), which was built

at Abarquh (in the center of Iran) in order to celebrate a mystic master.

In the eleventh century, constructing mausoleums officially became an important part of Persian architecture and culture. Most of these mausoleums were erected to honor famous Sufis and religious masters. The most important mausoleums and tomb towers, which were erected in the Seljuk era (1038–1194 CE), are Bayzid Bastami, Gunbad-i Sorkh, Ala-Aldin, Sultan Sanjar, Seh Gunbad, Jalal Aldin Husein, Davazdah Imam, Kharagan, and Pir. The tomb of Bayzid Bastami (ca. 1120), a famous Persian mystic in the ninth century, like other mausoleums was a place for pilgrimage. This building was later restored and developed in the fourteenth century. The tomb tower of Ala-Aldin (ca. 1149) followed the typical northern scheme, with 32 right-angled flanges and a conical blue-tiled roof, ornamented with an inscription frieze and a strap-work cornice band of the characteristic blue faience and terra-cotta. Davazdah Imam Mausoleum (1037) in Yazd has been regarded as an important structure in the history of construction because of the trilobed squinches, which were used in constructing its dome. This kind of squinch, a device that tackles the problem of placing a dome on a square chamber, creates the octagon to support the dome. The last and one of the finest examples of Seljuk architecture is Sultan Sanjar Mausoleum (ca. 1157–1160) in Merv; the mausoleum is a ponderous and solemn cubical chamber surmounted by a blue-tiled dome. The crucial transition from sanctuary block to dome above was achieved by means of corner galleries, which concealed the squinch. The circular drum of the dome is arched, and galleries mitigate the severity of mass without compromising the simplicity of the structure as a whole.

Cathedrals and Mosques

In Christianity and Islam, different requirements for each faith developed into different architectural types: the cathedral for Christians and the mosque for Muslims. A cathedral typically consisted of a long narrow nave with side aisles. This emphasized the procession and a focus on the clergy and the altar, which usually resided in an apse at the end of the nave. A cathedral may have also included a transept or cross aisle, a narthex, a baptistery, and a courtyard. Like the cathedral, a mosque was also a place for worshippers to gather but has no specific architectural requirements. A mosque can be anywhere Muslims pray. However, by the end of the first millennium, a basic typology had been developed for mosques. Mosques typically consisted of a roofed prayer hall, a qibla wall that indicated the direction of Mecca, a mihrab or semicircular niche within the qibla wall, a courtyard, and a minaret or tower for the call to prayer.

Cathedrals represented the main church or Christian worship space within a geographical area, called a see, and was headed by a bishop. The cathedral was the seat of the bishop and served as a center for worship. Other churches within each see accommodated additional worshippers and were subordinate to the main cathedral. Similar to Christian churches, there might have been many mosques within a city, but one was dominant in relation to the others and was called the Friday Mosque or Congregational Mosque. It was here that people gathered for Friday prayer, but it also served as the center of social and political life for the community. In theory, the Friday Mosque was to accommodate all of the men of a city for prayer.

Early Christians met in minimal structures, often houses. However, after Constantine's endorsement of Christianity, churches transformed from simple spaces to majestic edifices celebrating the new imperial religion of the Roman empire. The first church type developed from the Roman basilica, which consisted of a long central aisle with clerestory lighting that terminated in a semicircular apse and was flanked by narrower side aisles. In Roman basilicas the apse area was used to glorify the emperor or housed pagan cult

objects. In Christian architecture the apse came to be the location of Christ's representatives on earth, the clergy. An altar was located at the edge of the apse before the congregation, and a raised pulpit located to the side of the altar allowed the gospel to be read to the worshippers. The earliest churches were decorated with mosaics and paintings similar to that of pagan buildings with floral and faunal designs. Beginning in the fifth century CE, distinctly Christian ornament appears in such elements as crosses, depictions of martyrs, and Bible stories. The adoption of the basilica-type building allowed the church to accommodate a large number of worshippers within the structure and establish an architectural typology.

Constantine's first imperial church, which has been completely rebuilt, was San Giovanni in Laterano, Rome (320 CE). The original church consisted of a central nave, which was raised on columns to allow access to the double side aisles flanking the nave. A high clerestory window was located above each pair of columns and allowed light to penetrate the central space. The nave terminated in an apse where the altar was located, the inner aisles terminated in a wall, and the outer aisles led into a rectangular room on each side of the church. Its exterior was merely a simple expression of the interior spaces and reserved the splendor for the interior. The structure of the building was also simple, as it was constructed of concrete covered in brick, marble columns on the interior, and a simple wood truss roof covering each part of the church. This became the standard early Christian church.

Later cathedrals added a transept or cross aisle in front of the apse. This space could house a number of different functions, and in plan it caused the church to be shaped like a cross, which reinforced the symbolism of the church. An entrance or narthex was often added to the west end of the church. In the eighth through eleventh centuries this developed into a monumental entrance known as the westwork.

Like churches, the earliest mosques were also simple. Tradition indicates that the first mosque was located in the Prophet Muhammad's own house in Medina. It was a simple structure made from mud brick and palm tree trunks, as

was typical of that time. It consisted of a walled courtyard with small rooms for the Prophet's wives on the exterior of the courtyard. On the south side, there was a portico that sheltered the believers from the sun as they prayed. A second portico on the north side housed poor followers of Muhammad. Originally, the position of these was reversed because the believers prayed toward Jerusalem until 624, when Mohammed received a revelation to turn toward the Kabba in Mecca for prayer. This established Mecca as the direction of prayer for Muslims worldwide.

Other primitive mosques were constructed in Basra, Iraq (635 CE); Kufa, Iraq (638 CE); and the Mosque of Amr ibn al-'As, Egypt (641 CE). These consisted of little more than a demarcated space and protection from the sun. These mosques survive only in written descriptions, but the earliest surviving mosque is the Great Mosque of Damascus (709–715 CE). It was built within the walls of an ancient pagan temple. The Roman emperor Theodosius I (379–395 CE) appropriated the space for Christian worship, and after Damascus was captured by Muslims, it became a mosque. There are stories of the structure being shared by both Christian and Muslim congregations, but the configuration of space suggests that it was constructed as a mosque rather than adapted from a church. The prayer hall consists of a wide narrow space adjoining the entire south wall. Three nearly equal aisles run parallel to the long wall, and a raised transept bisects the prayer hall and creates a strong axis from the courtyard to the central mihrab. The remaining space within the pagan walls was reserved for a courtyard surrounded by a covered colonnade. At the corners of the original pagan walls, there were towers from which believers were called to prayer.

By the ninth or tenth century, the architectural type for a mosque was well established. Each mosque contained a covered prayer hall that was shallow and wide. Worshippers faced the qibla wall, which was aligned with Mecca, and a mihrab or semicircular niche drew attention to the qibla wall. A courtyard was located adjacent to the prayer hall to allow space for additional worshippers. Originally a man climbed on the roof of the mosque to call the believers to prayer, but later this function developed into a

tower called a minaret. Since Islam forbids iconography, there are almost no representations of humans or animals on mosques. Instead, Muslims developed intricate patterns using curving plantlike designs, abstract forms, and calligraphy to decorate their buildings.

The principal ways in which mosques and cathedrals differed was in their orientation and ornament. Mosques were wide shallow spaces, while cathedrals needed long narrow spaces to facilitate procession. Cathedrals lavished in depictions of saints, Christ, and scenes of Bible stories, while mosques deliberately abstained from the use of figural imagery and developed a rich tradition of abstract and geometric ornament.

Buddhist Monumental Sculpture and Architecture

As Buddhism spread from India to most of Asia, devotees refigured their environment into a sacred landscape of colossal statues, sprawling cave complexes, and elaborately arranged temples. Though Buddhism began to attract significant royal patronage within a few hundred years of its foundation in the fourth century BCE, during the period of the fourth to tenth centuries CE pious monks and kings who aimed to earn religious merit constructed awe-inspiring Buddhist monuments throughout Asia. The impetus to build these monuments derived from trade along caravan routes between India, China, and the Middle East, which helped the dissemination

THE LEGENDS OF SAMYE

Samye Gumpa was a famous religious site, reputed to have been the first Buddhist monastery built in Tibet. Architecturally, Samye symbolizes the confluence of three conflicting currents in Imperial Era (seventh to ninth centuries CE) Tibetan Buddhism: Tantric Buddhism, Indian Buddhism, and Chinese Buddhism. Two legendary events in the early history of Samye, the invitation of Padmasambhava and the Hwashang Mahayana debate, are interconnected with the symbolic architecture.

According to Tibetan ecclesiastical history, Tibetan emperors were originally adverse to tantric Buddhism being introduced to the country out of fear for its individualistic, nonhierarchal aspects. However, after native Tibetan demons repeatedly thwarted the efforts of the Indian Buddhist monk and philosopher Shantarakshita and the Tibetan emperor Trisong Detsen to found Samye, they invited the semilegendary Indian tantric Buddhist adept Padmasambhava to Tibet. Due to his magical tantric practices, Padmasambhava successfully suppressed the anti-Buddhist demons.

Samye's buildings are laid out to resemble a *mandala*, a symbolic microcosm of the universe. Among other purposes, tantric Buddhist meditators use mandalas as visualization aids. Therefore, the layout of the buildings at Samye represents the moment that the Buddhist religio-political authority began to embrace some tantric Buddhist practices. At the center of a tantric Buddhist mandala is often a deity in a multitiered palace. Samye's main temple is built to resemble such a palace, each level a different architectural style: Indian, Chinese, and Tibetan.

Samye Gumpa was a famous religious site, reputed to have been the first Buddhist monastery built in Tibet. As with much of Buddhist architecture, Samye Gumpa is constructed in numerous levels, symbolizing the passages through numerous lives as one ascends to enlightenment. (Lea Halevi)

At one point in the beginning of the Tibetan assimilation of Buddhism, Indian, Chinese, and central Asian Buddhist missionaries were welcome on the Tibetan plateau. However, in the late eighth century (ca. 792), followers of the Indian Buddhist monk Kamalashila arranged to have Hwashang Mahayana, a Chinese master of Chan (Zen) Buddhism, and his followers evicted from Tibet, an event mythologized as a debate won by Kamalashila. Whereas the layout of the buildings of Samye represent the moment that tantric Buddhism gained a foothold in Tibetan religion, the multiple styles of the main temple signal the official end of Chan Buddhist influence in Tibet.

—Cameron David Warner

of wealth and the spread of Buddhism. The monuments therefore served as not only educational and religious centers for local inhabitants but also destinations for pilgrims and the population basis for thriving markets.

Whether these monuments took the form of cave complexes, freestanding monasteries, or outdoor worship spaces, artisans adorned them with statues and murals of the Buddha Shakyamuni and other divinities. Though it appears

that the earliest forms of Buddhism prohibited the depiction of its founder, Shakyamuni, by the fourth century CE, the veneration of Buddhist statues had grown into one of the most important means to gain spiritual merit for a better rebirth. For the laity and monks, sculptures of the Buddha were not decoration but rather embodied his living presence.

These monuments also included many Buddhist reliquary shrines, called stupas. Stupas were

originally architecturally similar to burial mounds built for the purpose of venerating relics of the Buddha Shakyamuni's body. Over time, Buddhist devotional practices developed a complex theology based on the worship of the Buddha's body, speech, and mind. Devotees attempted to transform their own body into that of the Buddha through worshipping statues of the Buddha. They studied his speech through reading texts of his teachings and venerating the books containing them. Finally, Buddhists contemplated his mind through building and circumambulating stupas, which over time came to symbolize his mind. Statues of the Buddha and Buddhist stupas can vary in size from small enough to fit on a home altar to over 328 feet (100 meters) in height.

Though Buddhism continues to thrive throughout the world, the advent of Islam and its rapid spread to Asia were the death knell for the great period of Buddhist expansion and monument building. For many reasons, but especially due to iconoclastic and militaristic forms of Islam, Buddhism died in India, Afghanistan, and Indonesia, leaving some of its greatest monuments to be forgotten to world history until the era of European colonialism. Though some monuments from this period are still under serious threat, the vast majority are protected as UNESCO World Heritage sites and promoted by local peoples as tourist destinations.

Beginning in the second century BCE, in the present Indian state of Maharashtra 66 miles (106 kilometers) from Aurangabad, artisans carved the Ajanta Buddhist cave complex containing Buddhist monasteries (Skt. *vihara*) and reliquary shrine monument halls (Skt. *chaityagrha*) into the escarpment above the Waghora River. In the early period, there were only 5 or 6 caves, but Harisena of the Vakataka dynasty in the fifth century CE sponsored an additional 23 caves. These newer caves contain many statues of Buddhas and bodhisattvas. All of the pillars, decorations, and Buddha statues in the Ajanta caves were carved out of the living rock to form the cave.

When the second period of carving at Ajanta ended, artisans began carving the Elora cave complex 18.6 miles (30 kilometers) from Aurangabad. Though the complex grew to become a multireligious site of 35 caves, from the fifth to the sev-

enth centuries CE Elora consisted of 12 Buddhist monasteries, sleeping quarters, and kitchens.

About the same time that the Ajanta caves were expanded, the Longmen cave complex was established under royal patronage 7.5 miles (12 kilometers) south of present-day Luoyang in Henan province, in the People's Republic of China. Longmen is an immense sprawling site densely dotted along two mountain ranges, the Xiangshan to the east and the Longmenshan to the West with the Yi River between them. According to the Longmen Caves Research Institute, there are 2,345 caves and niches, 2,800 inscriptions, 43 pagodas, and over 100,000 Buddhist images. Most of the construction occurred during the Tang dynasty (618–907), but fully one-third were built during the Northern Wei dynasty (386–534). In these two dynasties monuments to Buddhism flourished across China, including the Yungang caves on the north cliff of Wuzhou Mountain in Datong during the Northern Wei dynasty and Mogao caves 15.5 miles (25 kilometers) from Dunhuang during the Tang dynasty.

Along the trade and pilgrimage route between Indian and China, present-day Afghanistan grew into an important Buddhist culture from the second to ninth centuries CE. Combining artistic influence from Greece and India, the two standing Buddhas of Bamiyan were carved out of the Bamiyan cliffs in 507 CE and 554 CE, measuring 120 and 180 feet (37 and 55 meters), respectively. The two largest carved standing Buddha images in the world, they were once decorated with gold and fine gems and surrounded by Buddhist monasteries and a thriving cave complex. Numerous Islamic iconoclasts attacked the statues, most notably the Mughal emperor Aurangzeb, but they survived complete destruction until 2001, when the Taliban succeeded in obliterating them with dynamite and heavy artillery.

Greater regional prosperity and Buddhist fervor finally penetrated the Tibetan plateau in the middle of the seventh century CE, where it soon gained royal patronage. By the end of the eighth century CE, the Tibetan emperor Trisong Detsen supported the construction of Samye, Tibet's first Buddhist monastery. Designed to include Indian, Chinese, and Tibetan architecture, the buildings of the monastery are arranged to form a mandala. The main temple is in the center of an area

demarcated by a circle that includes other buildings and four axial stupas. Severely damaged during the Chinese Cultural Revolution (1966–1976), Samye was rebuilt in the 1980s. In addition to being one of Tibet's greatest pilgrimage centers, it is a popular tourist attraction.

Another Buddhist monument built to resemble a mandala is the Indonesian Borobudur. Likely built around the beginning of the ninth century CE in central Java, Borobudur is a giant multilayered stupa that resembles a mandala from above. The monument was designed as a series of concentric circles with staircases and corridors ascending to the top that guide the pilgrim through an idealized image of Buddhist cosmology. Each level contains bas-reliefs carved in situ, 1,460 of which are narrative panels and 1,212 of which are decorative panels. Together these panels, derived from Buddhist canonical texts, instruct the pilgrim on the Buddhist law of cause and effect, the Buddha's life-story including stories of his previous births, and the perfection of wisdom. Though Buddhism died out in Java due to the spread of Islam, unlike Afghanistan, the Indonesian government has protected and preserved Borobudur for Buddhist pilgrims and tourists.

Arts and Material Culture in East, Central, and Southern Africa

The music, material art, and rock art of East, central, and southern Africa testifies to the creative abilities of Bantu-speaking peoples during this period. They created wood carvings, ceramics, metal jewelry, and beadwork. An important element of material culture among all the peoples in this part of Africa was that the line between beauty and practicality as spiritual meaning and everyday use were blended or non-existent. No art was made for art's sake, and no technological development was devoid of ritual and aesthetics.

The music of the Bantu-speaking peoples 1,700 years ago is what most people identify as African music, with polyrhythmic dancing, involving all parts of the body, accompanied by elaborate drum rhythms. Most Bantu-speaking peoples continued these music traditions right into the modern era, but in southern Africa the Khoisan-speaking peoples introduced the use of stringed instruments to accompany the drums. In northeastern Africa it was a different story. Around 800 CE Bantu-speaking peoples abandoned the drum and replaced it with the stringed instruments of their Southern Nilotic- and Southern Cushitic-speaking neighbors.

➤ ROCK ART AND LIVING SYMBOLS

Modern Western art is about individual artistic creation and often is described as art for art's sake, while the art produced by the peoples of East, central, and southern Africa during this era was created to represent a collective artistic aesthetic and always had a practical, social, and spiritual component. Woodcarvings, pottery, ceramic items, raffia weavings, bark cloth, jewelry, and rock art were decorated with symbols that corresponded to the religious and cultural norms of the societies. For example, throughout central and east-central

Africa there are many examples of schematic rock art and rock etchings, some of which date to thousands of years ago. The very symbols found in the schematic rock art, are found today on the walls of houses along the Luapula River and were painted by older women during the female initiation ceremony. Each schematic design represents an important element of a young woman's education, thus linking the artistic symbols of a much earlier period to those used today.

—Christine Ahmed-Saidi

All Bantu-speaking men excelled at wood carving. The distribution of carved wooden headrests is an excellent example of interactions of various peoples during this era. The Sudanic peoples of the Middle Nile Basin first carved the simple wooden headrests. Bantu-speaking peoples in the Great Lakes region learned from them how to carve headrests and then added their own elaborations. As Bantu-speaking peoples moved south they brought the headrests with them. By 500 CE these wooden headrests were carved by Bantu-speaking peoples from the Great Lakes to the southern savannas and west to the equatorial rainforests.

Pottery decorations have often been equated with the various cultures or ethnolinguistic groups that innovated and produced them; thus, each group had its own distinct pottery decorations. In the Transvaal region of southern Africa, from 400 to 700 CE the Shona- and Sal-speaking peoples created ceramic heads named by archaeologists as Lydenburg. These ceramic heads, reminiscent of the West African Nok heads of 1,000 years earlier, were probably used for initiation ceremonies. Other southern African Bantu-speaking peoples, especially those with cattle, stopped creating this ceramic art, possibly because of moving into areas where clay was less available or having a less sedentary lifestyle.

In graves dating to 500 CE archaeologists began finding metal jewelry, ceremonial axes, knives and hoes, and intricate iron staffs. Along the copper belt of Zambia and the Congo, copper jewelry was manufactured together with copper crosses that soon became the currency in central Africa.

The Khoisan-speaking peoples of southern Africa made beadwork from ostrich eggshells, but by 1000 CE the Indian Ocean trade networks had reached the Khoisan-speaking peoples, as evidenced by the appearance of glass beads in their jewelry.

Rock art is probably the best-known visual art of this part of Africa. In southern Africa, Khoisan religious leaders painted animals and humans in trancelike states on the caves and rock overhangs for thousands of years. In east-central Africa the Batwa peoples had long produced schematic rock paintings and etchings. By about 600 CE Bantu-speaking peoples had in-

Earthenware sculptures, possibly used as ritual masks in the Transvaal region of southern Africa, about 500 CE. Known as Lydenburg Heads, these objects display the Bantu potters' exquisite mastery of the craft. (Werner Dieterich)

tegrated the Batwa schematic rock art into their female initiation ceremonies. While the Batwa and the Khoisan used various natural color pigments, some of the later Bantu drawings were strictly in white clay, historically the ritual color among Bantu-speaking peoples. Women created the Bantu-made rock art in east-central Africa since it was a critical aspect of female initiation.

Early Medieval Chinese Painting

After the fall of the Han dynasty (206 BCE–220 CE), Buddhism entered China, flourishing during the Period of Disunity (220–589 CE). The arrival of the new religion influenced many aspects of Chinese culture, including that of art. Used primarily for the decoration of temples and caves, Buddhist painting styles during the Three Kingdoms period (221–280) introduced a new

➤ SIX LAWS OF PAINTING

Xie He (fifth century) was a highly influential art theorist of the Six Dynasties period. In his famous work the *Guhua lu* (*Evaluating Ancient Paintings*), Xie described a method of painting that ultimately had a huge impact on how later artists in China approached painting. Xie's Six Laws of painting were:

1. Breath Resonance: life and vitality embedded in the forms and lines of painting.
2. Bone Method: the way that the brush is used to structure form.
3. Responding to the Object: accuracy of representation to subject in the real world.
4. According with kind: accuracy of color and tone in rendering the subject's intrinsic qualities.
5. Organizing and planning: composition of the painting.
6. Transmitting and transplanting: manner in which forms are copied from one source to another.

Xie's Six Laws acted as the foundation for much of the painting theory that developed in China after the early medieval period.

—Anna Hennessey

Detail of an ink and color painting on silk hand-scroll entitled *Admonitions of the Court Instructress*, by Gu Kaizhi (about 344–406 CE). (British Museum, London, UK/Archives Charmet/The Bridgeman Art Library)

detailed and delicate style of painting images in China, differing greatly from the antique styles present in Han painting. As the Chinese domesticated Buddhism over the course of a few centuries, integrating the foreign religion with indigenous traditions such as Confucianism and Daoism, the thought, writings, and practices of Buddhism transformed on Chinese soil. Similarly, traditional Buddhist art forms that had originally developed in India also integrated with indigenous and secular forms of painting in China.

One painter in particular, Gu Kaizhi (ca. 344–ca. 406), from whom both paintings and works of writing remain extant, depicted subjects that were of both religious and secular origins. Gu, who lived during the Six Dynasties of China's Period of Disunity, is today often considered to have been one of the founders of Chinese painting. His textual work, *A Record of Painting Cloud-Terrace Mountain* (*Hua Yun-taishan Ji*), is a fundamental writing on Chinese painting theory, detailing a method of art that

advocates the transformation of emotion into form through the medium of painting. In the famous painting attributed to Gu, *Admonitions of the Court Instructress* (*Nushi Zhen*), light colors are brushed onto silk in the creation of Chinese figures whose flowing robes hang smoothly across the hand scroll. Whereas the compact lines of figures found in Buddhist art of the time may have influenced the composition of the painting, Gu's subject matter instead relates to the secular topic of lessons of virtue for ladies of the court.

Other masters of Six Dynasties figure painting include Lu Tanwei (active ca. 465–472) and Zhang Sengyou (active ca. 500–550), both of whose paintings of figures and animals exhibit some influences of Buddhism and Buddhist art, including that of three-dimensionality. In the meantime, Wang Wei (415–453) and Zong Bing (375–443) both painted landscapes and wrote important essays describing landscapes as extensions of the painter's own persona. The connection between artist and landscape, which

would have major significance in the works of later Chinese landscape painters, acted to ground landscape firmly within the field of Chinese painting.

Xie He (fifth century), an important art theorist of the Six Dynasties period, developed a theory of art that encouraged the use of six fundamental principles in painting known as the Six Laws. Xie's construction of his Six Laws was highly influential in the development of Chinese art over time, impacting subsequent theories and practices of painting in China. Along with the other major figures of his time, Xie contributed to the growing aesthetic discourse that was to become a central focus of later literati culture.

China was reunified after several hundred years of strife during the periods of China's Sui and Tang dynasties. Although the Sui dynasty (589–618) was short-lived, several important projects, including the Grand Canal connecting China's north to its south, were completed under the leadership of Emperor Yang (569–618). Zhan Qizhan (ca. 550–604), a painter from the north, and Dong Boren (active during the late sixth century to the early seventh century), originally from the south, met in the capital of Chang'an (present-day Xian), where they synthesized the northern and southern styles of Sui painting.

During the Tang dynasty (618–907), China greatly expanded its territories, economy, arts, and culture, ultimately becoming the largest and perhaps greatest empire of the Middle Ages. Literature, art, music, and calligraphy all flourished in the golden age of the Tang, centering around life in the cosmopolitan capital city of Chang'an. Throughout the Tang, painters made rich developments especially in the area of figure painting. Landscape painting, which would eventually replace figure painting as the dominant subject matter in later Chinese art, evolved more toward the end of the Tang. Yan Liben (ca. 600–673), a well-known figure painter of the early Tang, worked as an artist in the court of Emperor Taizong (599–649). Using a fine-brush style of painting, Yan's typical subjects included important political figures and events of the Tang. Fine ink and color brushstrokes of red and black dominate the silk hand scrolls on which Yan painted his subjects. Buddhism, which had be-

gun to flourish during the earlier medieval periods of China's history, continued to thrive during the Tang, and the religion makes a strong presence in the painting of Mid-Tang artists such as Weichi Yiseng (active in the late seventh century). This painter, who hailed from China's northwest area of Khotan and was most likely influenced by the Buddhist art of India and central Asia that had traversed the Silk Roads, utilized three-dimensionality in his depictions of Buddhist subjects.

During the Tang golden age (690–750 CE), one of the most important artists in the history of Chinese painting, Wu Daozi (ca. 680–760), began painting figures in sweeping brushstrokes that sought more to represent transcendent qualities of the subjects than to render the verisimilitude of their form through techniques such as three-dimensionality. Developing a simplified rapid brush style of an often monochrome ink, Wu Daozi, who like many of his contemporaries painted Buddhist subject matter, is also considered a founder of the liturgical painting within the Daoist tradition. The flowing style of Wu's brush would have a huge impact on the development of ink painting as it existed within both court and literati traditions of later Chinese art.

A final painter of the High Tang to have enormous influence on later art in China was Wang Wei (701–761), a poet-painter who developed a style of monochrome ink painting known as *pomo* ("splashed ink" or "broken ink"), which he used to paint landscapes. Completed in ink-wash instead of color, Wang Wei's works are described in the writings of later art critics as having utilized the myriad tones of ink to depict landscapes in a poetic fashion.

Early Medieval South Asian Art— The Pala School

The Pala School of Sculptural Art flourished from the eighth to twelfth centuries in north-eastern South Asia, roughly coinciding with the present-day states of Bihar and West Bengal and the nation of Bangladesh, interlinked by the Ganges River. Pala art is named after the dynasty under which it evolved and came to prominence. More than 6,000 sculptures in bronze and black stone survived to date, characterized by a high technical standard. The depicted fig-

ures are somewhat more sensual than in the preceding Gupta art. Females invariably have heavy round breasts and bulging hips, whereas males have broad shoulders and narrow waists. Facial features include more accentuated curves and somewhat harder edges. The themes were predominantly Buddhist (Mahayana, or the Great Vehicle), than Hindu and, to a much lesser extent, Jain. Pala art had a lasting impact on the Buddhist arts of Southeast Asia.

Pala stone sculptures are carved out of fine-grained black schist from the Rajmahal Hills and are often polished. Most stone sculptures are in high relief. The bronzes were usually gilded and often inlaid with silver. A typical Pala portrait of a divinity is as a central figure with two smaller attendants to the side, all three captured in an oval outline. Seated Buddhas are often surrounded by four or eight smaller Buddha images, representing different episodes in the life of the historical Buddha (Shakyamuni). Characteristic for the later period are huge steles portraying the Hindu god Vishnu with his two spouses, crowded with a multitude of minor figures and traditional background decoration around the central image.

Sculptures from the sixth through the early eighth centuries show the diagnostic features of the preceding late Gupta period (ca. 320–ca. 500) of north and north-central India. These are, among others, smoothness of the body, minimal jewelry, drapery that clings to the body, and a serene expression of the face with downcast eyes. New stylistic developments, indicating the early beginnings of Pala art, are more tubular arms, heavier and fuller bodies with broader shoulders, and straighter outlines of eyes and lips. During the ninth century and coinciding with the reign of the third Pala ruler (Devapala, ca. 810–850), Pala art can be considered mature.

Gradually, Pala art evolved toward greater iconographic complexity and focus on details. The bodies became longer with well-defined waists, the posture more static, and the faces more thin and pointed; dresses, jewelry, and background figures more finely carved and often highly complicated. A new invention was the crowned Buddha, adorned with jewelry, that first appeared in the eleventh century, perhaps

THE EXPORT OF PALA ART

During the Pala reign, Bihar was an international Buddhist center. For centuries, a vast number of travelers went to and from Bihar and its universities, monasteries, and sacred places. The region had been important for Buddhists since the fifth century BCE, as it included the ancient kingdom of Magadha, homeland of the Buddha. Important Buddhist centers of learning under the Palas were the universities and monasteries of Nalanda, Vikramashila, Somapura, Odantapura, and Jagga-dala. The often gigantic structures of their monasteries and universities were masterpieces of their time and inspired the builders of such complexes as the Borobudur in Java. They were built of burnt bricks and adorned with bands of terra-cotta and stucco panels along the many terraces. Sculptures were placed in shrines and in niches in the walls. Many visitors and traders returned home with smaller sculptures and manuscripts. As a result, Pala art exerted a profound impact on the Buddhist art of Tibet, Myanmar, China, and especially Yunnan, Sumatra, and Java.

—Alexandra van der Geer

related to the rise of esoteric Buddhism (Vajrayana, or the Diamond Vehicle). In time, Buddhism was gradually supplanted by Hinduism, especially Vaishnavism, which is reflected in the imagery of later Pala art.

From the end of the eleventh century onward, the Hindu Sena dynasty replaced the Buddhist Pala dynasty in larger areas. The style of their artworks is indistinguishable from that of the Palas, and sometimes the early medieval art of northeastern India is thus named Pala-Sena art. By the thirteenth century, Pala art ceased to exist in northeastern South Asia, in part due to Muslim domination in the area. Its influence, however, is visible in later Buddhist artworks of Tibet and Southeast Asia, including Sumatra and Java.

Painting and Sculpture in Christian Europe

Both painting and sculpture rapidly fell under the spell of the Christian Church in the early Middle Ages. Funerary art such as catacomb frescoes and sarcophagus sculpting typified public expressions throughout Europe, while illustrated books of the Bible blended Christian teaching with late Roman pictorial styles. After the legalization of Christianity under Constantine, the erection of churches provided extensive wall space for frescoes and mosaics that illustrated biblical narratives and depicted Christ in the role of ruler and judge of the world. Mon-

Chi-Rho page from the Gospel of Saint Matthew, from the Book of Kells. The Book of Kells is an illuminated manuscript of the Gospels, considered a masterpiece of Hiberno-Saxon style. (Jupiterimages)

umental sculpture declined with the Germanic invasions and Christian qualms about idol worship, but the conversion process necessitated the continued use of icons and illuminated manuscripts. Emerging monastic houses created many of these, blending late classical models with colorful, spirited, and often abstract forms adopted from Germanic and Celtic traditions. Irish monasteries sculpted high crosses, and Anglo-Saxons adopted the form as their own, in one case adding Christian poetic text in both Latin and Old English runes. Celtic monastic gospel books such as the Book of Kells and the Lindisfarne gospels featured clear Latin script encased in colorful decoration that ranged from tightly controlled geometric patterns to organically sinuous vegetable and animal forms. Many of the patterns echoed pre-Christian Celtic work in stone and metals. Painted figures reflected

traditions that included early Celtic stone carving and late classical and even Eastern Mediterranean illustration styles.

On the European continent some artists preserved late classical idioms, while Germanic artists continued in their native styles. Both worked with ivory and small-scale precious metals, while Christian book decoration held to its classical roots. From the mid-eighth century, however, Irish and Anglo-Saxon influence blended with these Mediterranean forms during the Carolingian Renaissance. Frankish king and emperor Charlemagne patronized artists whose work reflected the style of Christian imperial Rome as a way of linking his own empire with that of Constantine. This movement produced small-scale painted works and manuscripts with naturalistic human forms in clear settings but decorated with knot and zoomorphic patterning characteristic of insular art. While architectural sculpture remained primitive, generally limited to reliefs adorning doorways and column capitals, sculptors produced many intimate sculpted works in ivory, soft stone, and metals. The covers of presentation copies of illuminated Bibles and prayer books often featured finely carved abstract and figural motifs, sometimes incorporating antique carved gems or cameos. Limited evidence also remains of fresco mural painting, especially in churches. Figures tend to be large and fully formed, but realistic settings and interactions are lacking, evidence of the influence of early Christian models.

During the great disruptions of the tenth century German King Otto I sponsored a classically inspired imperial artistic revival (Ottonian Renaissance) similar to that of Charlemagne. Again artists harnessed classical forms and style to enhance imperial prestige, but the impact on broader trends was limited.

Early Medieval Hindu Religious Art

During the early medieval period (300–1000 CE), religious art played a key role in the expression of Hinduism throughout Southeast Asia and, particularly, India. Sculpted figures of gods and goddesses in bronze, copper, sandstone, and marble and ornately carved temples built to honor specific deities provided Hindus with earthly expressions of their beliefs. These artistic forms not only venerated the gods but also symbolized Hinduism's four goals of life: righteousness (*dharmā*), acquisition of wealth (*artha*), sensual love and pleasure (*kama*), and spiritual liberation (*moksha*). Nearly all of Hindu art is religious and reflects these life goals whether through fantastic personification of the many deities or a plethora of human forms.

The beliefs and practices of Hinduism defy definition as a single coherent religion. The pluralistic origins of Hinduism are complex, with no single sacred text, no particular founder, and no unified leader. Followers of Hinduism believe in reincarnation and karma (the law of return) and worship multiple deities. Hinduism is also a syncretic religion, which means that its practitioners integrate deities, symbols, principles, and practices from other religions, particularly Buddhism, Jainism, and indigenous and tribal communities.

Religious expression of Hinduism through art is equally complex. Hindu sculptures and temples built to honor and house deities during this period were pervasive throughout India and other parts of Southeast Asia. These pieces reflected everything from polytheism, political and social power, humanity's sensual nature, and peoples' relationships with each other and the gods. The symbolic meanings in Hindu religious art are multifaceted. They might represent humans' love for life and earthly pleasures, or they might symbolize humans' desire for union with the divine.

Hindu sculpture during the early medieval period immortalized and celebrated the human body and personified gods honored in the religion. As part of the Hindu four goals of life, sensual pleasure and spirituality are intertwined. *The Kama Sutra*, written in Sanskrit by the In-

ELLORA CAVES AT MAHARASHTRA

The Ellora Caves exemplify the fantastic Hindu temples built during the early medieval period. The 34 shrines, monasteries, and temples at Ellora, 17 of which were Hindu (Caves 13–29), were carved from the Charanandri basalt cliffs between 600 and 1000 CE. The site is located in Maharashtra, a state located on the western coast of India and home to Mumbai, the capital of Maharashtra and the largest city in India.

The Hindu, Buddhist, and Jain monuments, built side by side, demonstrate the religious tolerance of this period of Indian history. One of the Hindu temples at the site is the Kailash Temple or Kailashnath (Cave 16), built to represent the home of Lord Shiva. This freestanding monolith, originally covered in white plaster and resembling a snowy mountain, was carved from a single rock over a 150-year period. This magnificent temple required the removal of over 250,000 tons of rock to build and has been called the most outstanding piece of

Kailash Temple (Cave 16), at the Ellora Caves in the state of Maharashtra, India. (Jeremy Richards)

Indian art in history. The Ellora Caves are designated as UNESCO World Heritage Sites.

—Kim Kennedy White

dian scholar Mallanāga Vātsyāyana sometime between 300 CE and 600 CE, is a compendium on human sexuality. Hindu sculptures of the period drew inspiration from the *Kama Sutra* and reflected a preoccupation with sacred sexual union. Sculpted human forms typically presented voluptuous bodies in sensual movement and displayed overt eroticism and sexuality.

Images of gods and goddesses also dominate sculpture during this period. Major deities included the trinity of gods, Brahma, Vishnu, and Shiva. Brahma, the creator god, might be shown with four faces, each looking in one of the four directions. Vishnu, the preserver god, appeared as himself (as well as his other incarnations, particularly Krishna and Rama) engaged in combat or holding various ornaments. At times, he appeared with a boar's and lion's head on either side of his face; in other sculptures, he might have multiple heads with smaller human and animal attendants and weapons that represented the metaphorical battle between creation, preservation, and destruction.

The best-known iconographic Hindu sculpture is Shiva as "Lord of the Dance" (*Nataraja*).

Shiva, the supreme god, is depicted as a multi-armed figure engaged in the cosmic dance within a ring fire. The sculpture comes to life with rhythm and energy. His left leg is raised midair in flowing movement, while his right leg is balanced atop a demon, perhaps representing ignorance. In one of his right hands he holds a tambourine, and in a left hand he holds fire, energy that both creates and destroys. The sculpture illustrates Shiva's dual nature, both gentle and dangerous.

Some sculptures tell the story of mythical heroes and the victory of the gods over demons and other dangers. Demons are often seen multi-headed, showing their superhuman nature. The gods might be involved in cosmic battles. In one early medieval example from ninth-century India, the goddess Durga, shown as the multi-armed warrior, demonstrates her power and multitasking abilities, as each hand holds various weapons and tools.

Hindu architecture has brought the world some of the most awe-inspiring and ornate temples. The age of the Hindu temple cities began in 600 CE. Temples venerating the gods, most commonly Vishnu and Shiva, physically sat at the

city's center and were the heart of religion, politics, and society. Temples were believed to be inhabited by the god for whom it was built and was itself worshipped.

Construction of the temple was based on the cosmos. The architecture was designed on a grid of squares and triangles that formed a mandala, a circular patterned design that represents the universe. The temple, then, served as a three-dimensional structure that symbolized the cosmos, housed the god, embodied the god, and was the center of community religious and social life.

The temple was built on carefully selected sacred sites that best suited celebration of a particular deity. Typical Hindu temples of the early medieval period consisted of an entrance to the east, one or more halls, and an inner sanctum (*garbagriha*), with a tower built directly above.

The architecture and sculptures of Hindu temples are inextricable. The exteriors were covered in ornately sculpted figures. Within the sanctum (temple's center room) rested the linga, or phallic-shaped sculpture that symbolized the life force, typically dedicated to Shiva. The relief figures carved onto the exterior of the temple depicted various aspects of the temple's god or goddess, mythological creatures, and images considered auspicious such as loving couples (*mithunas*), musicians, and beautiful and sensual figures engaged in sexual practices.

The Hindu temples during the early medieval period were inspired by the *Puranas*, a collection of sacred Hindu myths and legends (and other religious topics such as rituals, festivals, and ceremonies), the earliest of which were compiled and written between 350 CE and 750 CE. The earliest medieval shrines were carved from rock like those at Ellora that contain Hindu shrines constructed between 500 CE and 1000 CE as well as the grand Kanchipuram temples (seventh to ninth centuries CE) and the Durga Temple at Aihole (seventh century CE).

Early Buddhist Art

Buddhist religious art was the world's most widespread class of religious artifacts in the first millennium CE. Produced in South Asia, central Asia, East Asia, and Southeast Asia—a region that extended from the Javan jungles to the peaks of the Himalayas and the deserts of Turkestan—Buddhist art found expression in cave temples, stupas, and other monumental art as well as in portable objects and the written word.

The earliest forms of Buddhist art were aniconic, or lacking in anthropomorphic images of the historical Buddha Shakyamuni. Common examples of these early representations of the Buddha included objects as diverse as a pair of footprints, a throne, or an umbrella, signifying royalty, and a tree, signifying the place where Shakyamuni achieved enlightenment. Scholars disagree as to what prompted the change to an iconic, or figural, representation of the historical Buddha, but there are two popular theories as to the source of the change. One argues for transmission of non-Indian Western sources via the Gandhara region of northwest India, while the other argues for indigenous development in northern India. Both concur that the Kushans, a nomadic group who ruled this part of India from the first through the fourth centuries CE, helped to disseminate early Buddhist imagery as well as early texts. Prior to the arrival of the Kushans, Buddhism existed as a largely oral tradition.

Early Buddhist architectural works centered on the stupa mound form, a burial tradition that predated Buddhism in India but found resonance within the Buddhist realm as a site for the cremated remains, or relics, of the historical Buddha. The stupa would continue to be the most commonly used shape for housing Buddhist relics throughout most of South and Southeast Asia

up to the present day. In East Asia the stupa would be transformed into a pagoda. Some scholars argue that the rationale for this was the inauspicious connotation of the funerary mound in China, where Buddhism first entered East Asia. Others argue that the new Buddhist religion sought a visible presence within China and adopted a very vertical and thereby noticeable form previously used only for watchtowers.

Buddhist art moved out of India and into central and East Asia via the Silk Roads, in actuality a series of routes traveled by merchants and monks through the Hindu Kush. Portable shrines as well as scriptures came into China via this route; similarly seagoing trade via the coastal routes of Southeast Asia further helped disperse Buddhist texts and images throughout present-day Indonesia, Thailand, Cambodia, and Vietnam.

Carved or cast, painted and printed, Buddhist imagery and sacred texts reached a wide audience through a variety of media. While the two main schools of Buddhist thought would diverge, with Theravada gaining prominence in South and Southeast Asia and Mahayana in East Asia, certain types of imagery can be found in both. Both schools would utilize large-scale Buddhist imagery, and both would feature illustrations of the life of the historical Buddha. The Mahayana tradition would later expand the pantheon of Buddhist images to include bodhisattvas, which are beings that have attained enlightenment but choose to forego nirvana in order to remain in this world to help others, and alternate Buddha incarnations, such as the seven Buddhas of the Past and the Buddha of the Future.

As Buddhism moved into East Asia, it entered into China and subsequently Korea and Japan often through royal patronage. The earliest known Chinese Buddhist images are found in second-century tombs, pointing to the incorporation of this new foreign religion and its imagery into the preexisting tradition of ancestor worship. Soon independent bronze portable shrines appeared, and temples were built to house works coming from abroad. The oldest Buddhist temple in China is the White Horse Temple (Baimasi) in Loyang, purported to contain the remains of two Indian monk envoys

➤ THE GUPTA INFLUENCE—EARLY BUDDHIST ART, 300–1000 CE

Within the study of Buddhist art, Buddha imagery created in the Gupta style is seen as the source for some of the most influential works found throughout Asia. Patronized by the great kings of the Gupta empire, Buddhist art created between the fourth and sixth centuries in India also reflected the regional diversity of the artists within the Gupta sphere of influence. The three main centers of Buddhist art of the Gupta era were at Mathura, Sarnath, and Nalanda, and through contact with Buddhist pilgrims and merchant travelers, the style of these regions spread throughout Asia.

The most noticeable feature of the Gupta style is the introverted, downward gaze of the Buddha figures along with a general softening and sensuality of form not seen in earlier Buddha imagery. After being brought into China, the Gupta style was transformed into what came to be referred to as the Tang International style, a combination of the sensual qualities of the Indian face with the heavily draped figure preferred in China. The Tang International style spread through the Korean peninsula to Japan, and extant examples of works bearing the Gupta influence are numerous. The Gupta style also was transmitted to Southeast Asia, where Buddhist statues seen at the site of Borobudur in Indonesia remain as testament to the power of the Indian influence upon it. Built around 800 CE, the complex of Borobudur includes 92 meditating Buddha figures carved from the local lava rock, yet their faint smiles, sensuous bodies, and downcast meditating gaze clearly show a knowledge of the Gupta style.

—Karil J. Kucera

who had brought the sutras and an image of the Buddha back to China in the first century CE.

Also imported into China for the first time was the idea of colossal imagery. The earliest such images are found at Yungang, west of present-day Beijing. The five colossal statues at Yungang were carved in the late fifth century from the living rock. Scholars contend that they were designed both to promote royal power and demonstrate filial piety. These works were followed by equally impressive royal creations at other sites in China, and as Buddhism spread to

Korea and Japan the idea of large-scale Buddhist imagery also emigrated. Remains of early royal projects in Japan include the colossal Vairocana Buddha statue found at Todaiji in Nara, Japan. Dedicated in 752 CE with an eye-opening ceremony, the Great Buddha at Todaiji suffered severe damage during the Gempei Wars of the late twelfth century but was rebuilt under the watch of Shunjobo Chogen (1121–1206). Since then the temple and its large cast bronze Buddha statue have suffered several setbacks, each time being rebuilt and recast. The only remaining original portion of the statue is the lotus base, with the statue now seated on it dating to 1692.

As Buddhism and Buddhist art settled into East Asia, the rationale for popular support shifted. In the early years, Buddhism generally entered these countries with state support; according to some scholars, these early acceptances of this new foreign religion were prompted by desires on the part of the various rulers to gain this-world benefit. The emperors of China and Japan and the kings of Korea all saw potential for strengthening their countries by allowing and supporting Buddhist practice. To this end, foreign monks accompanied the texts and images that came on what were largely diplomatic missions. These monks were seen as vital to proper usage of the images and texts, which ensured that these sacred objects would be effective. The monks were also instrumental in ensuring that the images were created in the appropriate standardized fashion and that the texts were accurately translated. In this way, new Buddhist teachings entered each of these countries sequentially as new schools of thought superseded old ones in India and China. Along with these changes, newly trained monks brought in the new images and texts necessitated by the new teachings. This transference of religious ideology and imagery in a succession of waves helps to explain stylistic and formal changes that occur in both the art and architecture found at Buddhist sites throughout Asia.

Buddhist Art on the Silk Roads

One of the most influential cultural items ever to have traversed the Silk Roads was the religious art of Buddhism, which migrated north from India, traveling across the Central Plains and arriving in China at the beginning of the first century CE. As Buddhism underwent significant theoretical transformations during the early years of the Common Era and the Mahayana school of thought developed from Theravada, India's earlier form of Buddhism, the religion's artworks, likewise spread in a variety of forms as they crossed the thousands of miles of land comprising the Silk Roads.

Ancient sites of Buddhism and Buddhist art began spreading across the Silk Roads before the beginning of the Common Era, flourishing between India and China by the mid-third century. Remnants of the art and material culture attached to Buddhist religion still dot the land today. Khotan, an ancient oasis town located along the southern edge of the Tarim Basin (of which the Taklamakan Desert is a part) and in what is now marked as China's southwestern portion of the Gobi, acted as one of the primary junctions along the Silk Roads through which Buddhist culture diffused. Several hundreds of miles north of India and Nepal, Khotan provided migrant Buddhist monks with a place where they could missionize, write, create art, and build monasteries. Xuanzang (602–664), the Chinese Buddhist monk famous for his travels and adventures to India, claimed that during the period of his visit in the mid-seventh century, Khotan was the most significant site of Buddhist practice along the southern route of the Silk Roads. He cited the existence of more than 100 temples and monasteries and more than 5,000 practicing monks and nuns in the city at that time. Archaeological excavations have revealed numerous Buddhist artifacts in and around Khotan and nearby Yotkan, an unearthen city that the noted Hungarian-British geographer and archaeologist Sir Aurel Stein (1862–1943) claimed to have been

Khotan's ancient capital. Artifacts found in these areas include fragments of Buddhist sculptures, tombs, and tomb art that included painted coffins, small figures and statues made of pottery and metal, ancient coins, wood carvings, and pieces of Buddhist architecture.

Other important oases skirting the Silk Roads southern passages eastward from Khotan and Yotkan include Niya, Lolan, and Lop Nor, all of which have offered archaeologists and historians rich sources of ancient Buddhist documents, textiles, and other artifacts similar to some of those found in Khotan.

Looking to the desert paths that move eastward toward China along the northern edge of the Tarim Basin, key features of Indian Buddhist art surface in the forms of carved grottoes, all of which mark caves found within the various hills and mountainsides of the region. Bamiyan, an oasis located west of the Tarim Basin in the heart of the Hindu Kush of modern-day Afghanistan, exhibits this same art form and was home to two of the most impressive Buddhist images of their kind to exist into modern times. One stood at 175 feet (53 meters), while the other raised to 120 feet (36 meters). Unfortunately, in March 2001 members of the Taliban who were acting on orders to eliminate artwork of Afghanistan's pre-Islamic past destroyed both statues, which had been carved into Bamiyan's sandstone cliffs around the third century.

The oases of Kucha and Turfan, also found along the northern edge of the Tarim Basin, share cave grotto temples similar to those of Bamiyan. Lying farther east, however, in China's Gansu Province, is the largest concentration of this kind of temple to exist in any area of the Silk Roads. Of these temples, the most famous is the Thousand Buddha Caves complex, also known as the Mogao Caves, located in the small town of Dunhuang, a critical junction along the Silk Roads and also a part of Gansu's gateway to China's imperial cities of Chang'an (present-day Xian) and Luoyang. Dunhuang contains China's most magnificent repository of Buddhist art. Along a cliff at Dunhuang that measures 5,577 feet (1,700 meters) 492 caves have survived, the vast majority of which are located along 3,280 feet (1,000 meters) of the complex's southern end. The earliest building at Dunhuang occurred

➤ DUNHUANG

Situated as an oasis within the Gobi desert and acting as an important trading post along the Silk Roads, the Chinese town of Dunhuang is famous for its Mogao Grottoes, which are known popularly as the Thousand Buddha Caves. The caves, which still exist today, house one of the richest stores of Buddhist art in the world. Painted murals of Buddhas, bodhisattvas, and other flying figures grace the cave walls. The different artistic styles found within the many murals reflect historical and cultural changes of artistic and religious importance. Double chins, for example, become prominent in the faces of some of the painted figures, representative of the aesthetic appeal that was popular during China's Tang dynasty (618–907 CE).

—Anna Hennessey

during China's Northern Liang dynasty (397–439 CE), when caves numbered by archaeologists as 267–275 were constructed. Inside the caves, many polychrome murals, thousands of clay statues and sculptures, and numerous other art objects have been found. Additionally, excavations have also revealed Buddhist scriptures in many languages as well as relics and objects of daily life representative of how the many people who practiced at, resided in, or passed through the sacred site, including nuns, monks, patrons, pilgrims, and artisans, lived their lives. The Buddhist sculptures and paintings at Dunhuang, many of which the dry desert climate of the Gobi helped to preserve, have provided scholars and visitors with one of the richest and most unique opportunities to view Buddhist art and life along the Silk Roads.

Buddhist art is found in many other important locations along the Silk Roads, and diverse artistic styles, from Greek to East Asian, influenced each other over time. Greco-Buddhist art, for example, flourished in Gandhara, a region of the Kushan empire (circa second century BCE–third century CE) and a key location along the western portion of the Silk Roads. Artists from Gandhara famously incorporated Greek realism into their styles of representing the draperies that clothed their Buddhist sculptures. The same styles were then transformed by the Chinese,

who created less realistic bronze statues of the Buddha at least as early as the fourth century CE. The syncretism of many of these styles become physically manifest in the wide variety of objects related to Buddhist practice and religious life. In addition to the artifacts mentioned here, Buddhist art also emerged on the Silk Roads in many other forms. Some of these include painting on silk, painting on clay, painted wood, painted earthenware, bronze figures, wooden scriptures, ink text on paper, sculptures, statues, relics, stupas, monuments, masks, jewelry, textiles, containers, vessels, pottery, caskets, and coffins.

Early Christian Art and Architecture

Sources both spiritual and cultural led to the flowering of religious art in the European and Byzantine late antiquity and medieval periods. Although the Hebrew Bible's injunction against graven images would seem to have been an obstacle to such development, Christianity believed itself to be sent into the world to go out in the world, and it quickly absorbed the architectural concepts and the artistic influences of Greece and Rome. Further, earlier Christian theologians had developed a theology of the incarnation that valued God's creation and, by extension, human creative expression. By the fourth century, when Christian emperors brought the rich resources of empire to monumental building, including

churches, the faithful eagerly took up their tools. For the next several centuries, they would produce churches, sculptures, paintings, and illustrated manuscripts, all of which told the story of salvation as they knew it from their sacred scriptures.

The great churches were built on the model of the Roman basilica. This building was rectangular in shape, had many columns, and was part of the business and market center of an ancient Roman city. Christian worship originated in Christian homes, but imperial support beginning in the fourth century both made it public and increased the need for larger spaces. Christians made a few changes in the Roman design to accommodate their liturgy. The side entrances of the classical Roman basilica, for example, yielded to a front entrance and a longitudinally oriented interior space leading to the altar in the front of the church. A few of the greatest examples are Santa Maria Maggiore in Rome; Sant'Apollinare in Classe, Ravenna; and Hagia Sophia in Constantinople.

These churches showed additional innovation. Rather plain on the outside, their interiors were covered with such artistic works as mosaics made from glass tesserae (small pieces or tiles) that were both brightly colored and resplendent in natural light. Although their debt to Greco-Roman art was obvious, they taught the faithful their theology by illustrating biblical episodes considered signal events in the Christian history of salvation. The most important artistic subjects were Jesus Christ and the Virgin Mary. The great mosaics of these two, such as those of Christos Pantocrator (Christ Almighty) or of Mary as Theotokos (God-bearer), showed the clear influence of earlier renderings of the Greek Zeus or earlier goddesses. In fact, a fifth-century report tells of an artist whose hand withered when he dared to portray Christ in the manner of the pagan king of the gods. The severe kingly rendering of the savior won the day nonetheless. Often this image is accompanied by words from the Gospel most readily associated with Christ's full divinity, John. In Byzantine churches, Christos Pantocrator often decorates the dome of the cathedral. Many images of Mary as the mother of Jesus survive. The Theotokos holds the Christ child. The tenderness of the mother-child relationship is evident in every image and befits the

devotion to Mary that was so strong during these centuries.

A later important architectural development was the monastery. In the civil and political breakdown that marked the end of antiquity, the monasteries provided refuge not only for monks and nuns but also for the intellectual heritage of classical civilization. Charlemagne showed particular interest in the monastery, and an ideal plan for one survives and is known as the Saint Gall Monastery Plan. Its central building was a church, next to which were the monks' sleeping quarters. A refectory for meals was nearby. The ideal plan also included a food cellar, a brewery, a school, quarters for guests, and several other buildings. The monastery at Cluny, built in the tenth century, became the model for monasteries built throughout Europe.

The preservation of the sacred text also provided occasion for artistic innovation. Irish monks, notably at the monastery of Clonmacnoise, illuminated hand-copied manuscripts, such as the *Book of Darrow* (seventh or eighth century) or the *Book of Kells*, an eighth- or ninth-century copy of the four Gospels of the Christian New Testament. These works are among the most celebrated pieces of monastic art and are counted as Irish national treasures today. In copying these manuscripts, the monks illuminated the first letters of sentences by painting them in gold, red, or another color with complex borders and designs of fabulous beasts, such as the unicorn.

Very few books from classical Roman and Greek civilization survived the destruction of the western Roman empire, but Charlemagne's coronation as emperor at the outset of the ninth century marked the beginning of renewed learning and attention to the production of illustrated manuscripts. The king wanted a learned civilization, and his cultural revival reproduced not only biblical manuscripts but also ancient Roman texts. These books showed a genuine intermingling of classical Roman motifs with Celtic and Teutonic dynamism. The new North European influence met with the classical world's balance and harmony and changed European art. One of the most famous of these manuscripts is the Utrecht Psalter (the Psalms). The liveliness of its representation distinguishes this example of Carolingian art from its earlier classi-

➤ EARLY CHRISTIAN ART AND ARCHITECTURE

From ancient times, kings and emperors have sought to impress and intimidate their subjects with monumental building. Its purpose was not only to show their earthly might but also to astound the populace with the power of the god whom they adored. The structures that survive often are considered among history's great works of art. Once powerful rulers embraced Christianity, the church benefited from this politico-religious drive. A few select examples follow.

The first Christian emperor, Constantine, built several churches, and among the most important were the Church of the Holy Sepulcher in Jerusalem, allegedly on the site of the tomb where Jesus was laid, and the basilica of St. Peter in Rome on the traditional site of the apostle's martyrdom. Constantine also constructed the church of Hagia Sophia in the new capital he named for himself, Constantinople. The sixth-century Byzantine emperor Justinian also built ambitiously. He renovated Hagia Sophia after bloodily crushing a revolt over his legal reforms and high taxation in Constantinople. The church had been damaged in the revolt, and so its rebuilding signified his victory. In the west, Charlemagne sought to hold together his empire through a network of monasteries. Consequently, he built a church at Aachen (Aix-la-Chapelle), where he was crowned by Pope Leo III, and also established a school there as part of his program of preserving and in many ways restoring the intellectual achievement of the Roman empire.

—Gerald S. Vigna

cal predecessors. As one example, the illustration of King David's confrontation with the prophet Nathan (2 Sam. 12:1-15) shows the cuckolded and betrayed general Uriah lying dead before them along with an illustration of the parable that the prophet recites to trouble the conscience of this ancient king. There is evidence that Byzantine artists were in the European court, and in the East talented artists also were commissioned by the emperors to illustrate books. They produced not only the Scriptures but also works of such important theologians as the fourth-century saint Gregory Nazianzus. The book of his homilies referred to as the Paris Gregory since it now resides in the *Bibliothèque*

Nationale in Paris contains many finely done images. The twin desires for creative expression and religious edification produced pictures not always readily connected to the text they illustrate. The Byzantines also produced books containing the four canonical Gospels. These Gospel books survive more than any other type; thousands still exist. They follow a standard format and begin with a sort of ancient concordance of the four Gospels. Each Gospel begins with an illustration of the evangelist, and they are richly adorned throughout with scenes from the life of Christ. A variant on this genre was the Gospel lectionary, which reproduced the text according to the readings in the liturgical year. The Christian art and architecture of late antiquity and the Middle Ages continued the heritage of Greco-Roman civilization. It also absorbed the influences of new tribal cultures sweeping across Europe and added its own genius in its need to be distinctly Christian.

The Iconoclast Controversy

Like many other world societies, Byzantine rulers and citizens believed that catastrophes were intended by God as punishment for their actions. They sought explanations for the disasters of the seventh and eighth centuries in religious beliefs or rituals that might be offensive to God. When Arab conquests of major Byzantine cities were accompanied by outbreaks of plague, the eighth-century emperor Leo III and his advisers decided that the cause for God's anger was the practice of venerating painted images of holy figures, known as icons, and banned their use. The Iconoclastic controversy (literally, "breaking icons") divided the Byzantine empire for a cen-

tury. Because Iconoclasm was eventually condemned as heresy, Iconoclast writings were destroyed. Since the sources for the controversy were written by iconophile monastic partisans after the restoration of icons, it is difficult to understand the beliefs of the Iconoclasts or the extent of their support.

Early Christianity inherited from Judaism the biblical prohibition against worshipping religious idols, and Christ was portrayed symbolically. But in late antiquity, people believed that divinity was directly manifest in the world, and Christians began to look to ascetics who could invoke God to protect them against illness, demons, or natural disasters. In the late sixth century, painted likenesses of Christ, the Virgin Mary, and saints began to fill this role. The subject of the image—Christ or a saint—was believed to become present in portraits painted on small wooden boards and to respond to the worshippers who could see and touch them. Famous images were carried in battles to protect the troops, and an image of the Virgin Mary was paraded around the walls of Thessalonica to save the city from a Slavic attack. Images of Christ and the Virgin Mary hung in public places, and people prostrated themselves, prayed, and burned candles and incense before them. A portrait of Christ was placed on Byzantine gold coins, and in 692 the Council in Trullo declared that Christ should be portrayed rather than represented symbolically. Was this the idolatry outlawed in the Bible?

Leo III banned the veneration of images about 730, and holy figures were replaced with crosses on church walls and coins. This must have seemed the cause for God's punishment of Byzantium. After years of civil war, Leo (717–741) and his son Constantine V (741–775), an ardent Iconoclast, had long and successful reigns. They began to win battles against the Arabs and, with the breakup of the Umayyad caliphate, even began an offensive against them. Constantine V developed theological arguments against icons, arguing that Christ's divinity could not be circumscribed in a painting, and in 754 a Church council condemned icons as heresy. When Constantine's son Leo IV (775–780) died in 780, his wife Irene, as regent for the young emperor, called a Church council to restore icons. Her

► IRENE—BYZANTINE EMPRESS

It has been said that life dealt Byzantine emperor Leo IV two cruel turns of fate: tuberculosis, a disease that killed him in his thirties, and his wife, Irene. Irene was a pious beauty from Athens who was consumed by a hatred for Iconoclasm. In 780, Empress Irene became regent for her young son Constantine VI and ruled Byzantium as co-empress for 10 years. She presided over a Church council that restored the use of icons. Later, she feuded with her son and eventually had him blinded, the standard punishment for political rivals. During 797–802, Irene ruled alone as the first female emperor. She negotiated alliances in the west and even considered a political marriage with Charlemagne before she was unseated by a rebellion of Iconoclastic soldiers. Irene's rule was controversial, but her power was unquestioned.

—Dorothy de F. Abrahamsee

Empress, imperial regent, and even emperor herself, Irene was an important and powerful figure in the Byzantine empire in the late eighth and early ninth centuries. In the Iconoclast controversy, she was an iconodule (supporter of icons) and incurred the enmity of the iconoclast army.
(Brian Snelson)

reign ended in failure, as she had her son blinded and was eventually exiled. Her successors presided over disastrous defeats at the hands of the Bulgars, and in 817 the emperor Leo V returned the empire to Iconoclasm. But the second period of Iconoclasm was less intense, and it was not accompanied by military victories. In 843 another empress, Theodora, presided over the restoration of icons to Byzantine churches, and the festival of Orthodoxy that commemorates it was inaugurated. Since that time, icons have always been an important part of Orthodox Christianity. Images of Christ and the Virgin Mary adorn church domes and apses, and painted icons portraying saints and the Virgin Mary in symbolic poses are a focus for private devotion in the home.

Historians continue to debate the origins and meaning of Iconoclasm. Some modern historians have interpreted Byzantine Iconoclasm as an attempt to restore the centrality of imperial reli-

gious authority or to attack the power of monks and holy men. Byzantine sources called Leo III “Saracen-minded,” implying that Iconoclasm was an idea taken from Islam. In the late seventh century figural art in religious settings was banned in Islam, and coins and mosques were decorated with Quranic inscriptions. Both societies were reacting to biblical injunctions against idolatry that they had inherited from Judaism. One indisputable outcome of the controversy is the artistic traditions that can be traced in icons and churches not only in Byzantium but also throughout the medieval Slavic world and Europe.

Buddhist Monumental Art in Java—Borobudur

Mahayana Buddhism has inspired some of the world's most impressive religious monumental art, such as the caves at Longmen in China and the now-destroyed statues of the Buddha in Bamiyan, Afghanistan, that stood 120 and 180 feet (37 and 55 meters) high, but the most impressive Buddhist monument is Borobudur.

Borobudur, the great Mahayana Buddhist stupa located in central Java near the confluence of the Elo and Progo rivers 25.5 miles (41 kilometers) northeast of Yogyakarta, was constructed in five stages over a period of years from about 780 CE to about 833 CE, and thanks to the numerous reliefs carved on the walls of its galleries and balustrades, it is a storehouse of valuable information about life in the general area during the rule of the Shailendra kings when it was built. In form a rather squat pyramid 103 feet (31.5 meters) high consisting of nine tiers surmounted by a great central stupa, Borobudur is situated on a hill rising from the surrounding

plain, but from the base of the stupa and from many points on the plain the three upper tiers, less steep in pitch than the lower portion of the stupa, are hardly visible; it is impressive not so much for its height but for its mass and wealth of architectural detail.

The ground plan of Borobudur is in itself a mandala (symbol of the universe), and the entire structure must be classified as a stupa rather than a temple since there are no open spaces inside where the worshipper can enter to pray or make offerings and since there are no relics enclosed in the stupa at the summit if the structure is a stupa of the *uddesika* (“commemorative”) type. There is no Buddha image inside this central stupa either, but on the three upper tiers or terraces, which are rather low and open to the surrounding mountains and sky, there are 72 subsidiary stupas arranged in concentric circles around the central stupa; in each of these stupas there is an image of a seated Buddha, his hands in the *dharmacakramudra* (“sign of turning the wheel of the Law”) position. The upper part of these stupas is in form like a bell completely covering the Buddha image on its base, but the walls of the bells are perforated with vents, lozenge-shaped on the two lower terraces and square on the highest one, a kind of stone latticework.

What may have underlain the unique concept of this structure, in essence really a vast open-air temple, is the custom of circumambulating a central image in the inner shrine of an enclosed temple or moving along a circular corridor in a temple with a solid core, for at Borobudur the worshipper enters the first tier at the east entrance, proceeds in a clockwise direction around that level, and upon reaching again the east entrance ascends the stairs to the next level and repeats this same circuit for each of the successive tiers. That it was intended that devotees were to be led by monks who would explicate the reliefs on the walls illustrating selected episodes in various Buddhist texts is attested by the fact that there are key words inscribed on various reliefs that would provide a cue to the guide for the appropriate commentary for each successive panel. Thus, the visitor to Borobudur would come there not only to worship but also to receive instruction.

There was another reason to carve reliefs on the walls of Borobudur in addition to leading

Buddhist temple of Borobudur on the island of Java, built in the ninth century by the Sailendra. (iStockPhoto)

the pilgrim to circumambulate the structure while receiving a lesson from the illustrations in stone of texts that he may have heard in sermons, and this is that by circling through this three-dimensional mandala, he was passing on the way through the three strata or spheres—*kâmad-bâtu*, or “the sphere of desire” (the base with hidden foot); *rûpa-dhâtu*, or “the sphere of form” (the four galleries); and *arûpadhâtu*, or “the sphere of formlessness” (the sixth tier and the three terraces)—and thus was participating in the mystical force of the mandala.

Though the Borobudur reliefs illustrate texts that were written in India about events that took place in India, the Javanese artists set these events against a background that was familiar to them. Of course, there might be reference in the texts to things that were typically Indian and possibly unknown to the artist, but considering the continued close relationship between the Shailendras and India, the Javanese artists must have been schooled in Indian artistic traditions and would have had access to pictures on paper as examples of these things. The pilgrim passing through the galleries of Borobudur would have recognized much that was familiar to him, especially since the artists, who had only very general directions for what was to appear on each panel to illustrate a specific portion of the text, perhaps delighted in filling in the empty spaces with details drawn from daily life, including people they knew and places they had visited, so that the observer would have felt perfectly at home passing through the course of the story as he passed through physical space.

All of this constitutes a rich source for the study of Old Javanese civilization and culture, as instructive in its way as the literature of the period and particularly instructive taken in conjunction with the literature, for these reliefs often show an item that is known only by name from the texts, and used in this way, the reliefs of Borobudur and other monuments of the period provide the pictures for the Old Javanese

vocabulary. Early studies of the Borobudur reliefs were concerned mainly with establishing the identity of the texts they illustrate and assigning the scene represented in each panel to a certain episode in those texts, but now that this tremendous task has largely been accomplished, scholars have more recently begun to try to interpret the reliefs not for their religious message but in synchronic (social) and diachronic (historical) terms. Certain inferences may be drawn from these pictures concerning institutions, though this is not always possible if we cannot identify the status or role of a figure from his attributes, but even though it is not always possible to identify certain objects, these reliefs are a mine of information about the architecture and realia of the Old Javanese period. There are about ten categories of items that are frequently represented in these reliefs and are of particular interest for further study: royal emblems and insignias, costumes and ornaments, dance movements and postures, musical instruments, vehicles, containers, furniture, buildings and architectural details, weapons, and ceremonies and customs. A detailed comparison of items within any one of these categories with corresponding items in India contemporary with and prior to the period of construction of Borobudur, as well as with those in present-day Java, should give some clue as to how much influence the culture of India had on Javanese culture of that time and to what extent those influences have survived.

Migration and Travel

Theme 3 discusses travel and migration during the seven centuries prior to 1000 CE. It deals with migrations as folk movements, migrations caused by wars, migrations over a few decades, and migrations over centuries and even millennia. This theme also discusses some ethnogenesis (the coming into being of new ethnicities) as well as ethnic and linguistic changes as they relate to migration.

After migration, Theme 3 discusses trade routes, trade diaspora communities, and religious pilgrimages.

Around 300–400 CE, the Bantu migration and dispersal, which began perhaps 3,000 years previously in the forests of West Africa, reached its limits on the shores of the Indian Ocean and among the Khoi-San-speaking pastoral peoples of South Africa. During these three millennia, the Bantu tide moved at a glacial pace, occupying the great equatorial forest, the mountains surrounding the Great Lakes and the Rift Valley, and the broad savannas east and south of the great forest. By 300 CE, they could claim nearly all the southern third of the African continent as their homeland.

In the Pacific another millennia-long human migration reached its limits about 800 years after the Bantu dispersal was complete. About 300 CE, eastern Polynesians sailing from the Marquesa Islands fanned out to settle Tahiti, Hawaii, and most of the other tropical islands in eastern Polynesia. Then there was another pause of 300–500 years before a settlement was made on subtropical Easter Island (Rapa Nui). After another pause of several centuries, settlement was planted, perhaps by 1200 CE, on mostly temperate Aotearoa (New Zealand).

At some undetermined time but probably between 700 and 900 CE, the Polynesian wave of exploration even reached South America, probably the coast of Peru and Chile. Two-way commerce between the Polynesian Islands and the South American coast probably continued for at least a few decades and perhaps a few centuries. Eventually, after about 1400, Polynesian long-distance navigation ended, and the Polynesian settlements on the South American coast were absorbed into the Native American population.

Although the Polynesian accomplishment in the eastern Pacific was most spectacular, that of another group of Austronesian speakers who crossed the Indian Ocean from Borneo to settle Madagascar also deserves our admiration. The settlers to Madagascar probably arrived there in the early centuries CE, but already Austronesian seafarers, from Champa on the Vietnamese coast as well as others from the Indonesian islands, had been sailing across the Indian Ocean to the East African

coast since the last centuries BCE. These Austronesian navigators sailed first across the Bay of Bengal to Sri Lanka. Then, rounding the southernmost promontory in that large island, they skirted the coast of India and South Arabia until they reached the East African shore. The Cham and other Austronesian seafarers discovered the pattern of the summer and winter monsoons and introduced the lateen square-rigged sail to Arab and Greek traders. The Austronesians traded along the coasts, and they were frequent visitors to the South Arabian port of Aden, the Ethiopian port of Adulis, and the East African port of Rhapta.

The ancestors of the Malagasy, who were the first settlers in Madagascar, sailed from Borneo and perhaps other Indonesian islands to East Africa sometime between 200 and 500 CE.

While the Malagasy were colonizing Madagascar, a process called the Great Movement of Peoples, or the Age of Migration (300–800), was unfolding in Eurasia from Mongolia to China and from the Eurasian

steppe to central Asia and Europe. Generally, these migrations were in the form of relatively impoverished and stateless forest and pastoral peoples migrating to wealthier agricultural lands ruled by large empires: China, the Roman empire, the Sassanian Persian empire, and the Gupta empire. What triggered these great migrations is the subject of continuing debate. Some attribute it to environmental factors, principally cold weather and drought, impelling pastoralists to seek new pastures

Generally, these migrations were in the form of relatively impoverished and stateless forest and pastoral peoples migrating to wealthier agricultural lands ruled by large empires: China, the Roman empire, the Sassanian Persian empire, and the Gupta empire.

and raid sedentary empires. Others find the cause of the migrations in the simultaneous weakness of all the great empires inviting the so-called barbarians in. Many of these barbarians were assimilated to the culture of the Romans and the Chinese. This includes most of the Germanic tribes who migrated to Spain, Italy, and Gaul (France, Switzerland, and the Low Countries), where they adopted the local Latin dialects. These dialects evolved, through the next 1,000 years, into the modern Romance languages. But in much of the Rhine Valley as well as Britain, there was little assimilation. The invaders imposed their Germanic dialects, which evolved into English, Dutch, Flemish, and modern German.

Likewise, the Slavic tribes who, in the sixth century, occupied much of the Balkan Peninsula, imposed their Slavic dialects everywhere except in the Albanian mountains, much of Romania, and Greece.

In China, the Five Barbarians (Xiongnu, Qieh, Xianbei, and the proto-Tibetan Qiang and Ti) occupied most of the north in the period 304–440. These barbarians ruled northern China under their Sixteen Kingdoms and immigrated heavily during this time but left almost no traces of their languages or culture. With them, assimilation was complete.

During the fourth and fifth centuries, while northern China experienced heavy barbarian immigration, large numbers of northern Chinese fled south to the Yangzi Valley and beyond. There the refugees established a southern Chinese empire, which endured, despite numerous regime changes, until 589. When the refugees from the north set-

tled in southern China, they dislodged indigenous peoples. Many of these displaced indigenous groups moved into less desirable mountainous land, but some, including Miaou (Hmong) and Thai groups, began a migration lasting centuries into Southeast Asia.

The weakening and collapse of these great empires were the invitation to the stateless and pastoral peoples to invade the great empires, but there was also a push from the Eurasian steppe. The period 300–1000 witnessed continued migrations/invasions of mounted pastoral peoples into the comparatively wealthy agricultural civilizations that lay to the east, south, and west of the Eurasian steppe. Until the early centuries of the Common Era, peoples of Iranian Indo-European speech dominated the steppe. But in the last two centuries, the Xiongnu, a non-Indo-European people from Mongolia, created a confederation that dominated the eastern steppe for four centuries. The Xiongnu empire posed the chief military threat to the Han dynasty, starting the process of driving the Indo-European groups, such as the Yuezhi, west and south.

From the eruption of the Huns to at least the fourteenth century, Inner Eurasia witnessed a steady migration of Turkish pastoral peoples from east to west across the Eurasian steppe to West Asia and Eastern Europe. These peoples included the Bulgars, the Avars, the Khazars, and the Turks. Some of these, such as the Khazars, established relatively long-lived empires. Some of these Turkish-speaking groups, such as the Bulgars and the Khazars, were assimilated by the conquered populations, but many, especially those in central Asia, assimilated the conquered populations to their Turkish language and ethnicity. Some Turkish groups, such as the Uighurs, stayed in Mongolia until the late ninth century and there created an empire in alliance with the Tang dynasty.

The great migrations that the Eurasian continent witnessed during the later centuries of the first millennium CE were replete with explorations of the Atlantic Ocean. The Scandinavian Vikings crossed the Atlantic to reach North America, while the Polynesians were voyaging across the Pacific. One branch of Vikings emerged from the shores of Scandinavia at the end of the eighth century to raid and pillage the coasts of western Europe, while another crossed the Baltic, where they penetrated the rivers of Russia to gather tribute and slaves. By about 1000 CE, Vikings had established at least one outpost in North America.

In the last centuries BCE, the one-humped Arabian camel (the dromedary) began to spread among the Berber tribesmen of North Africa. The Berbers then inhabited the grasslands north of the Sahara Desert. Using camels, the Berbers were able to voyage across the Sahara, that great inland sea of sand, even as the Polynesians were crossing the Pacific, the Malagasy were crossing the Indian Ocean, and the Vikings were crossing the Atlantic.

Some of the Berbers moved permanently onto the desert, where they became Tuaregs, the blue men of the desert. The ethnogenesis of the Tuaregs probably occurred in the first half of the first millennium CE.

One of the most significant events that produced migration as well as ethnic and linguistic change in Afro-Eurasia during this period was

the emergence of Islam. The rise and rapid spread of the Muslim faith in the seventh and subsequent centuries resulted in the migration of Arabs from Arabia to the far corners of the Muslim conquests: to Mesopotamia, Syria, and Palestine; to Egypt, North Africa, and Spain; and to central Asia. The Arab language, which prior to the rise of Islam had been a minor Semitic language, now rose to become one of the world's leading languages, on a par with Latin and Sanskrit. The Arabs were a small minority in all the lands to which they went, but because of the prestige of their language (and because the Arabs were in charge), the peoples in West Asia, Egypt, and North Africa eventually adopted the Arab language and culture and considered themselves Arabs. In Persia and central Asia, where Pahlevi and Sogdian had been widespread, Arabic initially made great strides, yet by about 900 CE, a new form of Persian emerged that was to become a leading Muslim language.

There were also many migrations in the Americas during this period, but the record and memory of most of these have been lost. In the early centuries CE, there might have been a movement of Arctic people from Asia, who introduced the bow and arrow to the Americas. It was probably during the first half of the first millennium that the Athapascans started their trek from the Arctic wastes eventually to the Four Corners region of the southwest. And the Arawaks during this period migrated from the headwaters to the mouth of the Amazon and from the Amazon Basin by way of the Orinoco to the islands in the Caribbean Sea.

All of these migrations stimulated and were stimulated by trade. One of the oldest and most used trade routes was the sea route around the southern and eastern shore of the Eurasian continent, from Spain to Korea and Japan. This can be divided into four or five interconnected segments: the Mediterranean, the Indian Ocean from Egypt to the west

coast of India, the Bay of Bengal and Southeast Asia from Sri Lanka to Indonesia, and the East China Sea from Indonesia to China, Korea, and Japan. Theoretically, a ship could, and perhaps some did, sail from East Africa or Egypt all the way to China, but almost all traders traveled in only one of these segments.

Theoretically, a ship could, and perhaps some did, sail from East Africa or Egypt all the way to China, but almost all traders traveled in only one of these segments.

Before 300 CE, "Greek" merchants from the Roman empire dominated the Indian Ocean trade, and they established trading settlements on the Malabar Coast of southwestern India. From 300 to 650 CE, Ethiopian merchants, based in the port of Adulis, played a large role in Indian Ocean trade. After about 650, Muslim Arab merchants dominated the trade, driving out the Ethiopians. The nearly simultaneous rise of the Tang dynasty and the Muslim caliphates created a powerful demand for luxury goods at the two ends of this trade route.

During this period, trade between the east coast of India and southeastern India burgeoned. Indian merchants settled in Southeast Asian ports, and Southeast Asian societies became Indianized. The Silk Roads was the second most important trade route. The Silk Roads is actually a metaphor, coined in 1877, to give a name to a complex of routes, all

running from China to the oases cities of the Tarim Basin and central Asia and on to West Asia and the Mediterranean world.

As in the ports along the maritime trade route, merchant diasporas from many lands settled in the cities all along the Silk Roads. Although there were other important trade routes in the Early Medieval Age, none equaled the Silk Roads as a cultural transmission belt. Other important trade routes included the three trans-Saharan routes, the Viking Baltic to Black Sea route, and, in western Europe, the slave route from the Slavic lands to the Mediterranean.

There were several trade systems in the Americas, but perhaps the most widespread was the Mississippian route by which the Mound Builders obtained obsidian, seashells, and copper. We know almost nothing about the travelers on this route.

Religious pilgrimage was another variety of travel that became more widespread during 600–1000 CE. The practice of pilgrimage had venerable roots. For example, pilgrimages to the Oracle of Pachacamac (the earth god) on the central Peruvian coast were a feature of Andean civilization from the early centuries CE. Long before the rise of Islam, the Kaaba in Mecca, as a shrine of Arabian polytheism, drew pilgrims from all Arabia. In India there were many foci of pilgrim devotion, and in the Roman empire pious Christians made pilgrimage to Jerusalem.

In the Early Medieval Age, pilgrimage became a long-distance affair, which crossed political and cultural boundaries. Fervent Chinese and later Korean and Japanese Buddhists made the pilgrimage to Buddhist shrines in India. These pilgrims, as well as Buddhists from Southeast Asia, often spent years studying at the monastery-academy of Nalanda in Bihar. Among the many Chinese Buddhist pilgrims, three left famous accounts of their Indian sojourns, which are invaluable resources for scholars studying medieval Indian history.

As well as pilgrimages to India, Buddhists, particularly from Korea and Japan, often journeyed to Chinese Buddhist monasteries and shrines to study. Pilgrimage also was prominent among Christians in Europe and Hindus, Jains, and Buddhists in India. Pilgrimage to Jerusalem continued to be a goal for the pious, but because of the chaotic international situation, fewer made this trip after 600. The foci of Christian pilgrimage came to be shrines where relics of Jesus or revered Christian saints were reputed to be stored. This pilgrimage was very effective in development of the Spanish Christian identity. In India, the pious traveled to revered shrines or temples. Varanasi, on the Ganges, was (and is) a chief focus for Hindu pilgrimage.

The Hajj, or Muslim pilgrimage to Mecca, has been the most important annual international cultural event since the second half of the seventh century. This journey of pilgrimage, which every year tens of thousands undertook from all parts of Dar al-Islam (House of Islam), served to promote a common Muslim culture and identity. The organization and protection of this great pilgrimage was one of the chief functions of Muslim governments.

The series of Japanese embassies to China from 607 to 838 were travel events that included political as well as religious, cultural, and

economic dimensions. These embassies were great well-planned and well-organized expeditions involving many ships and thousands of diplomats, students, and merchants. Their purpose was to study Chinese civilization in order to replicate it in Japan.

Migration and travel were becoming much more significant during 300–1000. Great migrations of peoples were very significant during the turmoil of the so-called Dark Age (300–650 CE), but during the Early Medieval Age (600–1000) travel for trade, pilgrimage, and cultural purposes became more prominent.

■ Introduction: Ethnic Migrations and Diasporas

Large-scale movement of populations, sometimes over extended periods, characterized the period 300 to 1000 CE. Perhaps the Bantu dispersal from West Africa to East, central, and southern Africa was the longest migration in duration, having commenced several millennia before this period. By the early centuries of this period this transcontinental movement was completed, and it changed the civilization of the eastern and southern Bantu.

Some of these Bantu crossed the Mozambique Channel to become part of the ancestral stock, with Austronesian immigrants from Indonesia, of the Malagasy people of Madagascar. Other Austronesian migrants during this period were the Polynesians who sailed from Tahiti and the Marquesas Islands to settle Hawaii, Rapa Nui (Easter Island), and the other Polynesian islands of the eastern Pacific, with the notable exception of New Zealand.

In the Americas, the Thule Inuit migration eastward from the Bering Sea coast along the Arctic Ocean littoral to Greenland and their replacement and/or assimilation of indigenous Dorset culture people was notable. Other important migrations in the Western Hemisphere were that of the Arawaks from the Amazon headwaters to the Caribbean Islands, the migration of Athapascans from Arctic regions to the northwest Pacific coast and southwest North America, and the movement of Teotihuacanos from their deserted city in the seventh century

to Maya areas and the subsequent Teotihuacization of Maya civilization.

In Eurasia, one of the earliest great population movements is known as the Great Movement of Peoples in Europe, which started with the Goths before 300 and animated German peoples, Huns, Slavs, Avars, Magyars, and others. It was a phenomenon that extended into the ninth century. At the eastern end of Eurasia, after 300, Turkish, Xienpei, and Tungus pastoralists surged through the crumbling defenses to settle in northern China. There, they maintained their ethnic identity only a few generations before the more numerous Han Chinese assimilated them into the Han ethnicity. When the “northern barbarians” poured into northern China, many Han Chinese fled to the south of the Yangtze Valley, where they displaced and/or assimilated the non-Han indigenes who lived there.

The other two major ethnic migrations/dispersals in Eurasia during this time concerned the migration of Turkish peoples from the Altai Mountains to central Asia, the Balkans, and Anatolia and the Arab diaspora throughout the Muslim world consequent to the emergence of Islam. The Turks changed the ethnic nature of central Asia, Anatolia, and other regions not so much by displacing the peoples among whom they settled but by the assimilation of Sogdian and other central Asian and Greek-speaking Anatolians into Turkish ethnicity and linguistic groups.

The Arab diaspora similarly assimilated large numbers of Syrians, Egyptians, Roman North Africans, some Berbers, and some Roman/Visigothic Hispanics into Arab ethnicity and language. One major exception to the Arab assimilation of peoples was the failure to assimilate Persian into Arabic ethnicity and language.

Turkish Dispersal from the Steppes

The history of Eurasia is characterized by migrations on an often vast scale and by the impact of those migrants upon the sedentary agrarian civilizations already established in the region. During the first millennium of the Common Era the most influential migratory episodes involved the dispersal of various Turkic-speaking confederations from the steppes of Inner Eurasia. The Turkish migrants at no stage constituted a homogeneous ethnic group, although they did all share a common language and a broad nomadic heritage. Despite their obscure origins, the Turkish dispersal profoundly influenced the subsequent history of Eurasia and laid the groundwork for the even more extraordinary impact that the Mongols would have in the twelfth and thirteenth centuries.

The name “Turk” appears for the first time in Chinese annals dated to 542 CE, where it is used to refer to a nomadic people who were in control of a substantial steppe empire stretching from Mongolia to the Black Sea, the first Turk empire (ca. 552–81). This Oghuz Turkic entity was forced to accept Chinese hegemony in the seventh century (leading to a degree of Sinotization), although in 683 Turkic forces under the leadership of Kutlugh recaptured much of the original realm, establishing a second Turkic empire (963–734). The oldest known Turkic inscriptions (dated to the 720s) were produced

➤ TURKIC MIGRATION'S IMPACT ON WORLD HISTORY

The migration of the Turks into western Eurasia had a profound impact on subsequent world history, which although outside of the chronology of the period between 300 to 1000 CE needs to be noted. Islam spread rapidly as a result of privileges and advantages made available to converts by the Seljuks, and by 1453 when the Seljuks' successors the Ottomans conquered Constantinople, Anatolia was a Turkish and Islamic realm, which it has remained ever since. The Ottomans' disciplined military organization allowed them to not only become masters of the former Seljuk and Byzantine realms but also to go on and found a world state (the Ottoman empire) that eventually controlled a vast region stretching from Vienna to the Indian Ocean and from North Africa to the Caucasus. A separate wave of Turkish migrations also played a significant role in the history of India. During the eleventh century the Ghaznavid Turks of Afghanistan were led by Mahmud of Ghazni on a series of raids into India. Over the ensuing centuries they consolidated their hold until eventually the Turkish sultanate of Delhi controlled much of northern India. Mahmud and his successors actively (and violently) promoted Islam at the expense of Buddhism and Hinduism, and the long-term impact of this Turkish invasion was the establishment of a significant Muslim presence in northwestern India.

—Craig Benjamin

during this period. The ruling elites recorded the creation myths of the Turks and accounts of their early history in a series of inscriptions on funerary stele near the River Orkhon in northwestern Mongolia. This inscription of the powerful qaghan Bilga Qaghan and Prince Kül Tegin illustrates both the imperial vision and military and organizational prowess of the Turks: “When the blue sky above and the dark earth below were created, human beings were created between the two. My ancestors Bumin Qaghan and Istami Qaghan rose above the sons of men. Having become their masters, they governed and established the empire and the institutions of the Turkic people. They had many enemies in the four corners of the world, but waging military campaigns, they subjugated and pacified

them, making them bow their heads and bend their knees.”

In the mid-eighth century the Oghuz Turks entered a period of decline, eventually losing control of their empire to the Uighur and (later) Kyrgyz peoples. The Oghuz migrated to the southwest, settling in Sogdiana. The Turkic-speaking Uighurs were probably not related to the Oghuz ethnically, although they were the most dominant of the Tokuz Oghuz (or “Nine Tribes”). The Kyrgyz were the last Turkic-speaking peoples to dwell in Mongolia, and after their expulsion in 924 by the Manchurian Kitai, some of their tribes followed the Oghuz by migrating to the south and west.

In western Inner Eurasia meanwhile, two other influential Turkic empires emerged during the second half of the first millennium, those of the Avars and Khazars. Fifth-century Byzantine sources refer to mixed Turkic-speaking groups dwelling and raiding along the borders of the Balkans, which the sources name as “Bulghars” or “mixed ones.” From the 520s on, Christian missionaries were active among these Turkic/Hunnish groups, and Byzantine negotiators used Turkic Pecheng escorts and hostages to maintain trans-Pontic trade routes. In 557, a Turkic-speaking people of East Asian Hunnic ancestry who called themselves Avars migrated into the western steppes. Eventually the Avars occupied the old Hunnish heartland of Pannonia, where their oppressive policies encouraged massive Slavic migrations into the Balkans. As the Avars began to adopt a sedentary lifeway in the seventh century their power declined, and they suffered a crushing defeat in 626 with the failure of an ill-conceived attack on Constantinople itself.

A new Turkic-led Khazar confederation then appeared in the region of the northern Caucasus. Initially allies of Byzantium, the Khazars began raiding to the south in a series of attacks described in Armenian histories. In the 670s Khazar forces defeated “Great Bulgaria” and emerged as the major power of the Caucasus, although their military strength was tempered somewhat by the periodic attacks of Arab Islamic armies. By the mid-eighth century the Khazar empire had become a major Eurasian power in control of a substantial region that included the Kazakh steppes, the Caucasus, and the steppes and for-

ests of the Volga, Don, and Dnieper river systems. In the late ninth century the Khazar elites converted to Judaism, although the bulk of the population remained Christian, Islamic, or pagan. The Khazars were able to withstand various challenges to their power (from the Magyars, Pechengs, and Volga Bulghars) until the late tenth century, when a Rus army under Prince Svyatoslav destroyed Khazar power for good.

Farther to the southeast, migrants from the second Turk empire of the eastern steppes who had settled on the fringes of the Abbasid empire began to adopt the religion of Islam. The Arab conquest of Sogdia in the seventh century had brought the Oghuz Turkic clans of the region (including the Seljuks and Osmanli, ancestors of the Ottomans) into direct contact with the Islamic caliphate of the Abbasids, and by the tenth century they had largely embraced the Sunni Muslim faith. This conversion was of great historical significance, because as the Turks continued their migration they carried their new faith with them, helping to expand the influence of Islam throughout western Eurasia.

By the second half of the tenth century, large numbers of Seljuks were being employed as mercenaries by the Abbasids and had settled within the borders of the Abbasid realm. But the Turks became increasingly powerful until by the mid-eleventh century they overshadowed the authority of the caliphs. The Seljuk leader Tughril Beg (990–1063) was proclaimed sultan by the Abbasid caliph, and by 1055 he had gained control of Baghdad. This was the beginning of two centuries of Seljuk dominance in the region, and as Turkish control widened and strengthened, the Abbasid caliphate was reduced to a figurehead role. Tughril Beg’s successor Alp Arslan (r. 1063–1072) led the Seljuks on invasions of Georgia, Armenia, Syria, Palestine, and Anatolia. As substantial numbers of Turkish peoples migrated into Anatolia (the heartland of the Byzantine empire), conflict between Alp Arslan and the Byzantine emperor Romanus IV became inevitable. In 1071 the Seljuks inflicted a devastating defeat on the Byzantines at the Battle of Manzikert, which opened up much of the Byzantine empire to Turkish occupation. Alp Arslan’s son, Malik Shah (r. 1072–1092), proved himself an able administrator, but early in the twelfth century the

substantial Seljuk empire began to fragment, and eventually many of the Seljuk states were overrun by Chinggis Khan and the Mongols.

The Great Movement of Peoples in Europe

The great migration of peoples in Europe, a process that historians have often called the barbarian invasions, was a critical factor in the transformation of the ancient world into medieval Europe. Beginning in the fourth century CE, groups of peoples moved from eastern Europe and the Asian steppes to settle within the territories of the Roman empire. Current research suggests that these peoples did not overwhelm the Roman population by numeric superiority but instead introduced their cultural identities into an already divided imperial society. By providing opportunities for the rejection of Roman control, the immigrant tribes were the catalyst for the fragmentation of the Mediterranean worldview of the Romans. The arrival of northern and eastern peoples eventually led to the permanent division of much of the Roman empire into separate kingdoms, each with its own languages and customs.

The migrations arose in response to the Roman empire's involvement with tribes beyond its frontiers. As a source of luxury goods and lucrative employment in its armies, Rome had a magnetic effect on many non-Roman peoples. Between the first and third centuries CE exposure

Burning of a city under Attila the Hun. Initial from a French manuscript, fifteenth century. (Alinari/Art Resource, NY)

to Roman training, tactics, and wealth also made the tribes into more formidable military opponents. Unlike the divided Gallic chieftains defeated by Julius Caesar in the first century BCE, tribal leaders of the third and fourth centuries CE assembled large groups of followers, gathering the traditional kinship-based clans and tribes into large confederations such as the Alamanni and the Goths. In 376 groups of Goths crossed the Danube without Roman approval, beginning the great migration of tribes into the Roman empire.

Invasions by steppe peoples from central Asia, especially the Huns, convinced the Goths and other Germanic peoples to seek permanent protection within Roman territory in the later fourth century. Third-century tribal confederations had raided Roman provinces along the Rhine and Danube and then returned to their homes beyond the rivers. However, the Huns and other nomadic steppe peoples moved into eastern Europe in the fourth century and disrupted more settled tribes such as the Goths in the Ukraine. Pressure from the east meant that the Goths wanted new homes safe from Hunnic

➤ ATTLA THE HUN

Attila, the king of the Huns from 445 until 453, became the most infamous tribal leader and enemy of the Roman empire during the migration period. He not only united the Huns, nomadic Mongolian tribes who had invaded eastern Europe, but he also incorporated Iranian and Germanic peoples whom the Huns had dislocated. With this large multitribal army, he carved out a vast empire in central Europe, laying claim to territory from the Ukraine to the Rhine River. Attila overcame several Roman armies and sacked many important cities, but his greater goal was to intimidate the Roman government into giving him money and recognition of his rule. Attila suffered a setback in 451, when the Romans defeated his army with their own coalition of allied tribes at the Battle of the Catalaunian Plains (Châlons), but only his death following a wedding banquet in 453 spared the Roman empire from further threat. Without his ferocious leadership, Attila's great tribal confederation disintegrated within a few years of his demise, but his exploits elevated him to legendary status as the "Scourge of God."

—Craig H. Caldwell III

raids, not just the plunder that earlier raids had provided.

In response to tribal pressures on its frontiers, the Roman empire attempted to incorporate the incoming peoples into its provinces as Romans and to resist the immigrants with force. The Goths had first entered Roman territory with permission to enroll in the army, but the numbers of immigrants overwhelmed the local food supply and imperial supervisors, and groups of Goths then plundered the Balkan provinces to support themselves. In 378 a Roman army attacked the Goths at the Battle of Adrianople, but the bands of Gothic warriors inflicted a severe defeat upon the Roman forces and killed the Roman emperor Valens. After several more years of war the Roman government granted the Goths the right to settle in certain regions of the Balkans. The Goths won permission to live within Roman territory on terms of their own making. But tribal leaders demanded

further concessions from Rome, and feuds between western and eastern Roman emperors left their armies unable to compel Gothic obedience. When the Roman emperor Honorius failed to satisfy the Goths' demands for better land and imperial employment, the Gothic king Alaric invaded Italy and sacked the city of Rome in 410.

As Roman strategies to co-opt or contain the tribes failed, Roman control in Europe went into retreat, bringing about the dissolution of the western Roman empire. But despite contemporary accounts of barbarian invasions, the migrating peoples did not actually conquer the Roman empire by force. Internal Roman conflicts offered the tribes a great opportunity. Civil wars induced Roman emperors to pay large subsidies to the tribal kings to frustrate their opponents, and distracted Roman rulers also failed to manage their western provinces effectively. In this political vacuum of the late fourth and early fifth centuries, the kings led their tribes across the Rhine and Danube frontiers and settled among the Roman population as the new power brokers. The Visigoths (western Goths) and Sueves established themselves in Spain, the Ostrogoths (eastern Goths) in the Balkans and Italy, the Vandals in northern Africa, the Anglo-Saxons in Britain, and the Burgundians and the Franks in Gaul (France). Some Roman provincial leaders even encouraged tribal immigration to protect the residents, and emperors became dependent upon tribal leaders to provide much of their military strength.

During the Hunnic invasion of the Roman empire in the mid-fifth century, the defense of the provinces reflected the importance of the newly settled tribes. To oppose Attila the Hun's army of subject peoples, the Roman general Aetius assembled his own coalition of tribes in northern France. The addition of the Visigoths and their king Theoderic to the allied forces proved decisive, and the Romano-Gothic army triumphed over the Huns in 451 at the Battle of the Catalaunian Plains (Châlons). The Roman contribution to victory was management, not weapons or tactics. Despite Aetius's genius for forging alliances, he became another casualty of intraimperial competition when the emperor Valentinian III had him murdered in 454. The

fall of Aetius foreshadowed the final irrelevance of the western Roman emperor, for when the ruler could not organize the tribes and arbitrate among them he became a puppet without his last claim to independent leadership. After the tribal king Odoacer invaded Italy and forced the boy emperor Romulus Augustulus to abdicate in 476, he dispensed with the need for any Roman emperor at all. The western Roman provinces had all become kingdoms of the migrating peoples, and the Roman empire in the west ceased to exist. Many Romans came to identify themselves as members of the migrating tribes since the new ethnic identities conferred tax exemptions and legal privileges. The tribes did not obtain their kingdoms by conquest so much as they had taken over control of local affairs from the Roman government and absorbed the resident populations.

The Slavs were a different type of migrating people from the Germanic tribes that preceded them. They did not have significant economic ties to the Roman empire, and hence they did not incorporate Roman political and economic structures as readily as other groups. Rather than being drawn into Europe by the Huns, the Slavs initially expanded in the East European voids left by Hunnic disruption and Germanic emigration in the fourth and fifth centuries. From the Ukraine the Slavs migrated both to the northwest, settling in Poland, and to the southwest, entering the Balkans. Early Slavic culture did not support complex political organizations like the Germanic kingdoms but instead favored smaller tribes centered on hilltop strongholds.

After the Hunnic empire of Attila collapsed in the mid-fifth century, the Slavs gradually emerged as a dominant presence in southern Europe. By settling along the Danube, they came into contact with the eastern Roman (or Byzantine) empire as well as the Avars, a nomadic steppe people from central Asia who had moved into central Europe after the Huns. As a subject people of the Avars after 576, the Slavs fought in their armies and established tribal centers wherever Avar expeditions drove out the Romans. Since they expanded in the shadow of Avar devastation, Slavic culture was slow to mix with that of other peoples, and the political organiza-

tion of the Slavs remained relatively unsophisticated into the seventh century. This very local nature of Slavic society attracted people displaced by the frequent wars in the Balkans, and archaeological investigations suggest that the Slavic identity was the most commonly held in the region.

When Avar authority began to weaken in the mid-seventh century, the Slavs rebelled and established fledgling kingdoms. Service alongside the Avars had transformed the Slavs into formidable warriors, and the Slavic revolt against the Avars produced their first independent, complex political units. In the eighth and ninth centuries Slavic influence expanded into Greece and to the alpine frontier of Italy. Slavic languages became the common tongue in southern and eastern Europe, even influencing the language of neighboring non-Slavic peoples such as the Bulgars. The Bulgars, a nomadic steppe people who spoke a Turkic language, had crossed the lower Danube in the late seventh century. Within their kingdom of fortified encampments centered around modern Bulgaria, the Bulgars subjected some Slavs to their control but also adopted a Slavic language in their literature. The Slavs' demographic and cultural success led to their eventual dominance in much of Europe even though they had not inherited effective political control.

Slavs Move West and South

Slavic tribes spread roughly from the fifth to the eighth centuries from eastern Europe toward the west and south and created individual states. They entered central Europe and the Balkans,

THE HIGH-WATER MARK OF SLAVIC EXPANSION

The high-water mark of Slavic expansion is in the Peloponnese peninsula of Greece and perhaps in the present-day Netherlands, places that today have few traces of Slavs. Slavic dialects were spoken in several villages in southern Greece until recent centuries. In the Peloponnese, a number of villages even retained Slavic names until the 1930s, when they were changed to Greek. In the west, the Slavic tide may even have reached the Netherlands, where a place named Wiltenburg near Utrecht was regarded by medieval writers as a castle of the Veleti and then, from the fourteenth century, connected in history literature to the Slavic people. Some groups of Slavic people could have reached this area. This remains a hypothesis (by Libuše Hrabová), which is difficult to test because the archaeological sites have been destroyed.

—Antonin Kalous

areas once inhabited by Germanic tribes, or parts of the Roman empire. They mainly cultivated the land but were also warriors who made terrible attacks on the lands south of the Danube. After settling down, however, they formed early states, which gradually became integrated in the European culture and became part of the Christian tradition both in the west and in the south.

Slavs are Indo-Europeans who originated in eastern Europe, probably between the Vistula, Dnieper, and Dniester rivers. They developed close relations to the Baltic tribes, ancestors of the modern Latvians and Lithuanians. The Slavs became distinct tribes during the period of mass migration of Germanic tribes at the fall of the western Roman empire. They are often identified with Veneti, a tribe so-named by Roman authors in the first and second centuries. The Slavs started to move from their homeland about 500 due to economic developments, growth of the population, and mass migration. There were a few tribes who went farther east (or stayed in the original place) and later formed the Eastern Slavs (the ancestors of the Russians, Ukrainians, and Belorussians). However, the movement westward and southward had more immediate consequences for European history.

Slavic tribes began to be registered in Byzantine sources in the sixth century (Prokopios, Jordanes); they were taking part in Byzantine campaigns, and Slavic tribes lived north of the lower Danube and the Black Sea. From the beginning of the sixth century they also made frequent assaults on the lands south of the Danube. The Slavs moved from their original land to most parts of central, eastern, and southeastern Europe. In the beginning of the sixth century they crossed the Danube and settled in the original area of the Roman empire. In the lower Danube area they were integrated in the Avar forces from the 580s up to the siege of Constantinople in 626. The cooperation with these nomads led to the Slavic assimilation of the Avars. In the Balkans the Slavs assimilated the Turkish Bulgars to form the Slavic Bulgarian kingdom. Slavic tribes, not yet differentiated, had occupied the western Balkans (later Croats, Serbs, Macedonians, and farther northwestern Slovenes) as well as central Europe (later Czechs, Poles, Slovaks) with the Elbe basin (Sorbs and other tribes).

The move westward is confirmed by archaeological finds (i.e., ceramics of the Prague type) from present-day Slovakia, Moravia, Bohemia, Poland, and parts of Germany from the mid-sixth century onward. The Slavs, however, spread farther to the west: archaeological finds prove their presence in northeastern Bavaria. These Slavs were closely related to the Sorbs, one of the tribes that inhabited the areas between the rivers Oder and Elbe (Polabian Slavs). The first statelike formation in this area was under the rule of Samo (d. 658/659), which, however, is not very well attested. A contemporary chronicle describes him as a Frankish merchant who settled in the Slavic territory and led a tribal federation in defense against the Avars, whose power rose in the 630s. The same chronicle speaks of a conflict with the Frankish king Dagobert.

The Slavic expansion brought a new population to areas vacated by Germanic tribes and destroyed areas of the Roman empire. Slavic migration posed serious dangers for the original inhabitants, subjecting them to murder, enslavement, and other atrocities. In the long run the Slavic nations created strong individual states,

which changed the political, social, cultural, and linguistic milieu of central and eastern Europe.

Traffic in Slavic Slaves

The west and east European slave trade in the early Middle Ages was largely connected to the Slavic peoples. They were quite often taken prisoners in the incessant wars and sold as slaves in Crimea, wherefore the name “Slav” became a common name for slaves. The Slavic slave trade spread in other parts of Europe as well and diminished only after the tenth century, when almost all the Slavic nations became Christian.

The importance of the early Slavic slave trade, which was organized mainly by the nomadic Khazars during the sixth to ninth centuries, is attested by the common name for slaves. The Khazars, who converted to Judaism, became the main exporters and merchants in terms of the Slavic slave trade, the main area of the trade being the Black Sea. Later on this stream of slaves was taken over by Mongols from the thirteenth century. There were also the Swedish Vikings who participated in the slave trade in eastern Europe, buying slaves among the Slavs and bringing them to Constantinople. The trade in the Mediterranean in general was also concentrating on slaves (Slavs were mentioned), as Abu al-Qasim ‘Ubayd Allah ibn Khurradadhbah, a Persian scholar, in *The Book of the Routes and the Kingdoms* (between 846 and 886) describes.

The conflicts between Slavic tribes and early Christian states in central and east-central Europe also meant a new influx of slaves (usually as war prisoners) in the west, especially from the ninth century and the wars of Charlemagne and his successors. The main trade routes, which were also used for the slave trade, were along the Danube and the Elbe at that time. From the mid-tenth century the most significant

➤ WAS THE SLAVE TRADE THE BASIS FOR THE CREATION OF THE BOHEMIAN KINGDOM?

Some modern Czech historians claim that the slave trade helped to lay the foundations of the Czech state. The Prague slave market was renowned all around Europe, and the Bohemian dukes, by bringing the Slavic slaves from the East (as captives), earned a considerable amount of revenue, but there were other merchants who earned much more (the possible price of a slave in Catalonia was about 13 times higher than in Prague). It is, however, characteristic for all the new states of central Europe, including Poland, Hungary, or even the emerging German empire in the tenth century, that they profited in their early stage from the Slavic slave trade and based part of their economy on it. These profits helped finance the armies that were indispensable for any emerging state.

—Antonin Kalous

trading place in slaves in the western Slavic countries was Prague, capital of the newly emerging Bohemia. Ibrahim Ibn Jákub, a Jewish merchant from Cordoba, refers to slaves among the export articles from Prague to the South (Muslim and Jewish traders).

The Slavic slave trade started to diminish in the tenth and eleventh centuries when almost all the Slavic peoples had accepted Christianity and when several of the rulers promulgated laws to limit the slave trade. The slave trade in these areas (especially present-day Ukraine and Crimea), however, continued to exist into the seventeenth century, when the most significant slave markets were the Muslim countries. By the thirteenth century slaves became uncommon in western Europe north of the Pyrenees.

Migrations of the Anglo-Saxons and Scots

By the early medieval period the inhabitants of the British Isles were not a homogeneous group but rather an aggregation of distinct cultures sharing a common lineage with those continental Europeans who expanded into the British Isles following the Ice Age. The coming of Julius Caesar and the Romans in 56 BCE and the subsequent partitioning of early Britain established the conditions that would classify the perceived differences among the islands' peoples. The people of southern Britain largely came to be known as the Angli (the English), while those north of the Roman frontier of the Antonine Wall (stretching from the Firth of Forth to the Firth of Clyde) were generally known as the Picti (the Picts), or painted people.

The people of Ireland, known to the Romans as the Scoti (the Scots), extended their reach into western Scotland in the fifth century. By 500 CE these Scots had consolidated their holdings into the kingdom of Dal Riata, comprising most of western Scotland. The eastern portion

of the country was largely the domain of the Picts, although Britons from the south and Angles from the southeast also contended for land and power in the border regions.

In the meantime, the Visigoths had sacked Rome in 410 CE, and the Roman emperor Honorius recalled his forces from their outposts in the British Isles. The native Britons in the south, now lacking the protection and discipline of their Roman occupiers, faced hostile incursions from almost every side. The Celtic Scots and Picts attacked from the north, the Welsh held the west, and Germanic raiding parties from the continent threatened the eastern shores. The Britons' solution was to employ the services of Germanic mercenaries to drive off the hostile Celtic forces. Generally, these hired warriors came from three continental groups: the Jutes and the Angles from Denmark, and the Saxons from northern Germany.

Although these mercenary forces were successful in protecting the Britons from their enemies, they soon recognized the extent of their employers' weaknesses and began to settle in England. The Jutes dominated Kent and surrounding areas of the southeast, while the Angles and Saxons made their homes in East Anglia and the northern Midlands. The Scots and Picts largely retreated to Northumbria and above, and the Welsh remained ensconced in the west.

The Britons, however, were not destroyed by these Germanic newcomers. Rather, a process of cultural assimilation and accommodation began that lasted throughout the Anglo-Saxon period. British and Germanic people and cultures blended and coalesced into relatively distinct cultural groups that became known as the Anglo-Saxon Heptarchy. These seven kingdoms were the precincts of Kent, Sussex, Wessex, Essex, East Anglia, Mercia, and Northumbria. Yet even these seemingly stable entities changed size and character as they struggled against one another and suffered continued raids by Scandinavian war parties. Eventually, even these Viking raiders would settle in the Danelaw of the Midlands and East Anglia. It was not until the reign of King Aethelstan (924–927) that all of these groups would be ruled as a cohesive Anglo-Saxon (English) people.

—Todd Preston

➤ LIVING WITH VIKINGS

Although the Anglo-Saxons themselves could claim Germanic invaders as their ancestors, this does not mean that they were happy to see the process begin again in the ninth century. However, despite the turmoil of the period and the bad press the Vikings endured in the *Anglo-Saxon Chronicle*, these Scandinavian invaders did more than just pillage and run. Much to the dismay of the residents of Anglo-Saxon England, the Vikings stayed.

What may have begun as scattered raiding at the end of the eighth century eventually became an influx of settlers who, for good or ill, had an important impact on the character of the emerging English nation. When King Alfred (r. 871–899) accepted the surrender of the Danish king Guthrum (ca. 886), Alfred allowed Scandinavian law to operate in a limited fashion within an area known

as the Danelaw. The Danelaw extended north from the Thames on the eastern side of the country as far up as Northumbria, effectively splitting Anglo-Saxon England in half.

However, the Danes in England came to be more than an encamped military force. They settled and tilled the land, and their influence on English culture can be seen from the names of northern towns to the Scandinavian focus of the epic poem *Beowulf*.

Magyar Migrations

Hungarian history before the tenth century may be described as a series of migrations ending in the Carpathian basin, the westernmost stretch of the Eurasian steppe. Hungarians (or Magyars) are of Finno-Ugric origin (their closest relatives are Voguls and Ostyaks, small tribes now living in the northern Urals), and the nation itself presumably developed somewhere in the southern

parts of the Ural Mountains. From there they moved west, for some time lived north of the Black Sea, and finally came to Pannonia (the plain on the Danube where present-day Hungary is located) in the end of the ninth century.

The Magyars started their journey in the southern Urals, the traditional site of their ancient home (Magna Hungaria). There they had lived for centuries in close contact with Sarmatians and Scythians, and the Hungarian language contains some loan words from these Iranian peoples. Around 600 CE they began moving west and gradually settled north of the Black Sea, where they were initially tributaries of the Khazar empire. By the late 830s they revolted against their Khazar overlords and ruled the steppe north of the Black Sea for more than half a century. In the 870s they are described by Muslim merchants, whose information then passed to accounts of Muslim scholars (e.g., Ibn Rust, Gardizi). The Magyar settlement around the lower Dnieper was called Etelköz, a name probably brought from their former settlement closed to the Volga (Atil). In these areas they met with Turkic tribes, who contributed about 300 words to Hungarian.

From their base north on the Dnieper they sent raiding parties west. They served as allies of Bulgaria against the Byzantine empire and of

➤ BROTHER JULIAN FINDS THE MAGYAR'S ANCIENT HOMELAND

The Magyars never forgot that they originally came from the East. The stories of the prequest period and the migration were always present in the Magyar legends, including the fights in Etelköz when the Magyars were defeated by the Pechenegs. After the failure of the Crusades in the Holy Land they began looking for their ancestral homeland so that they could Christianize their relatives on the Eurasian steppe. When the establishment of the Mongolian empire made a journey to the steppe less dangerous, four Dominican friars traveled east in 1234–1235. Only one of the monks, Julian, came back and gave an account of the journey. He said that he found the territory called Magna Hungaria and spoke Hungarian with the natives.

—Antonin Kalous

Great Moravia against the Franks. Their first attack on the eastern Franks is attested in 862. From that time they acted as a member of the political game in east-central Europe, as allies of the Great Moravia against the Franks, and alternatively as allies of Byzantium and the Franks against Moravians and Bulgarians. In the late ninth century the Pechenegs, a coalition of Turkic pastoralists, invaded the Black Sea steppe and drove the Magyars westward. In 894 they left Etelköz, crossed the Carpathians, and settled in Pannonia (895–896).

Magyar warriors, however, continued their attacks on Europe. They helped in the destruction of Great Moravia but also attacked more distant lands. They entered Italy, Germany, the Iberian Peninsula, and France, often as allies of some local lords. In all the places they wreaked havoc on the local population. Their raids on the west finally ended in 955, when they were decisively defeated by the German king Otto I close to Augsburg.

During the tenth century the majority of the population settled in Pannonia. For about two or three generations they continued living as nomads, but by 1000 most of them became sedentary except for their seminomadic way of

herding the cattle. In Pannonia the Magyars would erect the Hungarian kingdom in the eleventh century.

The Settlement of Eastern Polynesia to 1000 CE

The exploration and colonization of the remote islands of eastern Polynesia was a remarkable episode in human prehistory. Movement into the margins of eastern Polynesia represents exploration and migration of the last habitable lands ever to be settled by humans. Originally colonized from a homeland in western Polynesia, the ancient seafarers moving into eastern Polynesia relied upon sophisticated oceangoing vessels (double-hulled canoes) and reliable navigational systems based on observations of the sea and the sky. These Polynesian navigators crossed a vast ocean using traditional navigation techniques long before European explorers ever attempted to do so with the aid of modern navigational equipment. The initial settlement voyages into eastern Polynesia were of remarkably long distances and required the transport of humans, plants, and animals in order to establish viable colonizing populations. Once settled, the isolated islands of eastern Polynesia offered diverse natural environments, which the first settlers adapted to and eventually modified over the long term.

Settlement of eastern Polynesia involved colonization of a vast region known as the Polynesian Triangle, which stretched to the Hawaiian Islands, New Zealand, and Easter Island (Rapa Nui). Eastern Polynesia includes all of the islands and archipelagos to the north, south, and east of western Polynesia (Tonga, Samoa, Futuna, and 'Uvea). The central core of eastern Polynesia is comprised of the Society Islands, the Cook Islands,

POLYNESIAN DISPERSALS, 300–1000

the Tuamotu Islands, the Austral Islands, and the Marquesas Islands. The margins of eastern Polynesia, settled from the central core, are more remote and include Pitcairn-Henderson, Mangareva, Easter Island, Hawaii, and New Zealand.

Western Polynesia was the first part of Polynesia to be settled and is now considered the immediate homeland from which eastern Polynesia was colonized. This contradicts earlier theories that saw the origins of eastern Polynesian cultures as outside of the region, usually Asia or the Americas. The timing and direction of human dispersals out of western Polynesia into central and marginal eastern Polynesia have been the subject of continued debate. Most researchers use material evidence for human settlement, including direct evidence for human occupation (radiocarbon-dated cooking features) and indirect or proxy data for human settlement (human-induced environmental change inferred from pollen cores). Linguistic data and historic

data such as oral traditions, myths, and genealogies are also important for reconstructing the regions' settlement history.

When voyagers first set off from the western Polynesian homeland into eastern Polynesia is a highly contentious issue, and consensus has yet to be achieved. Most archaeologists accept that there was a long pause of at least 1,000 years between the settlement of western Polynesia (ca. 1000 BC) and eastern Polynesia (sometime in the first millennium CE). This was perhaps because colonization of eastern Polynesia required greater navigatory skill that needed to be built up over time or because of climatic factors such as availability of suitable winds for sailing east.

Settlement models utilizing data on experimental voyaging and prevailing winds, current archaeological data, and linguistic evidence support a similar order for the settlement of eastern Polynesia. The Society Islands were settled first, and then one migratory branch moved through

➤ SWEET POTATOES AND POLYNESIAN CHRONOLOGY

Sweet potato ultimately originated in South America, but it has long been an important staple food item in Polynesia, indicating that it was a transpacific introduction. How exactly was sweet potato first brought to Polynesia, when did this occur (i.e., was it brought by the first Polynesian colonists, or was it a secondary introduction, either by Polynesians or by European explorers), and why was it introduced? Our present data indicates that this tuber was introduced during the prehistoric era into Polynesia through the dispersal of human agents.

There is no doubt now that sweet potato was first domesticated in the Americas, most probably central or northern South America. Ethnohistoric and linguistic evidence suggests that the Polynesian word for sweet potato, *kumara*, comes from Ecuadorian people who were intensive sweet potato cultivators.

When it was first realized that sweet potato originated in South America and was introduced into Polynesia, one argument was that sweet potato was an early prehistoric introduction into Polynesia, arriving as early as 700 CE. Other evidence suggested that sweet potato may have been a later introduction, perhaps brought by European explorers. In the last 20 years, fragments of carbonized sweet potato have been found in several eastern Polynesian archaeological sites. These include well-dated prehistoric contexts in Mangaia (Cook Islands), Easter Island, and the Hawaiian archipelago. Archaeologists now accept that sweet potato was imported into central eastern Polynesia by 1000–1100 CE and most likely spread into the margins of eastern Polynesia during 1100–1200 CE. Sweet potato is then a secondary introduction, brought to eastern Polynesia several centuries after the region had first been colonized but many centuries before European contact.

The question remains as to whether natives from South America brought sweet potato to Polynesia or whether Polynesians made contact with South America and returned with the sweet

potato. Most agree that it was Polynesians, rather than South American voyagers, who made a two-way voyage and were responsible for the initial transfer of sweet potato, given the extensive evidence for long-distance voyaging capabilities for Polynesians. After this initial transfer to eastern Polynesia, this food item spread westward into central Polynesia both by Polynesian and later European traders. The prehistoric circulation of sweet potato within eastern Polynesia and to the west broadly supports that eastern Polynesians were carrying out long-distance voyaging up until 1400 CE and that some of these voyages included contacts with eastern Polynesia.

But why was sweet potato adopted when Polynesians already had a series of good crops? It is quite similar in appearance to yam, which already was a Polynesian cultivar when sweet potato was introduced. However, unlike yam, sweet potato can be planted year-round, and thus it was easily adopted by Polynesians who already had experience with a similar food crop. Some have argued that perhaps a canoe load of east Polynesians were taken off course by a large storm and landed in South America. Once there, they would have sought out foodstuffs such as sweet potato that were similar to plants they had already cultivated. They then brought sweet potato back to eastern Polynesia with them on their successful return voyage (likely as a foodstuff to eat on the voyage). Once they returned, they had leftover sweet potato that they continued to cultivate and trade because the plant had a high yield and was well adapted to Polynesian styles of cultivation.

the Tuamotu Islands to the Marquesas and then up to Hawaii. A second southern migratory branch passed through the Tuamotus to Pitcairn-Henderson and out to Easter Island.

Many archipelagos in central eastern Polynesia lack well-excavated archaeological sites with

accepted chronologies, and researchers often rely on archaeological and linguistic evidence. Some have argued that the central eastern Polynesia corridor was settled between 0 CE and 600 CE, while proponents of a shorter chronology believe that the area was not settled until after

600 CE. Early sites in the centrally located Society Island archipelago include evidence for domesticated coconuts at 600 CE. Because this island group is subsiding, the earliest human occupations that would have been situated on the coast are now under water, making the discovery of early settlement period sites in the Society Islands nearly impossible. Indirect evidence for human occupation (forest fires, increased erosion) in Mangaia, Cook Islands, may date to 500 BC–0 CE, but this evidence is not accepted by all researchers. Additional archaeological excavation in several archipelagos will be needed before the sequence of dispersal into central eastern Polynesia can be determined with any accuracy.

It is well accepted that the remote eastern Polynesia area was settled out of an eastern Polynesian homeland in the central corridor. Historically, all eastern Polynesian cultures share certain traits, including a pantheon of four gods (Tangaroa, Tane, Rongo, and Tu) and a ritual architecture complex including ceremonial spaces delineated by stone enclosures (*marae*) and stone platforms. They also share oral traditions, namely creation myths recounting a marriage between a Skyfather and an Earthmother from whom the rest of the gods are born, and from them came human life. These traits are not all shared by western Polynesian cultures. Tangaroa, the creator god, is found in western Polynesia, but the remaining gods in the pantheon are cultural innovations found across eastern Polynesia, as is the elaborated ceremonial architecture. These shared innovations found throughout eastern Polynesia suggest some period of isolation from western Polynesia while they were being innovated. It is currently accepted that these traits were early innovations developed in the settlement of central eastern Polynesia. They later spread to marginal eastern Polynesia once voyagers moved out of this secondary eastern Polynesian homeland situated in the central eastern Polynesian corridor.

Currently available archaeological data supports this sequence, indicating that sites in the margins of eastern Polynesia were settled after those in the core. The chain of islands stretching from the Australs to Mangareva, Pitcairn-Henderson, and finally to Easter Island appears to have been settled no earlier than 800–1000 CE based on archaeological evidence, although some

would argue that it was one to two centuries later. Current archaeological data suggests settlement of the Hawaiian archipelago no earlier than 800 CE. New Zealand was the last part of Polynesia to be settled by humans, at 1200 CE. Chronologies privileging archaeological and linguistic data support a somewhat earlier movement out of the Society Island-Tuamotuan region at 600–800 CE, with expansion up to Hawaii and down to Mangareva, Pitcairn, and Easter Island.

While the chronology is still hotly debated, researchers now agree that the settlement of eastern Polynesia was the result of purposeful long-distance voyaging rather than by accidental drift voyaging. Computer simulations and experimental voyaging with double-hulled canoes have established that eastern Polynesia was settled intentionally by voyagers with an amazing range of navigational abilities for way finding and landfall. DNA evidence from New Zealand Maori skeletal populations indicates that at least 70–190 women must have landed in the first voyage to this island, indicative of a well-planned voyage of several large double-hulled canoes rather than a small fishing canoe being blown off course during a storm.

Early settlements in eastern Polynesia were nucleated villages situated on the coast, and often these hamlets are found on sand dunes. Houses were of both round-ended and rectangular shapes, and cooking areas were separated from the dwelling. The first human colonists brought domesticated animals (pig, dog, and chicken) and horticultural crops (taro, yam, banana, breadfruit) and relied heavily on indigenous land and sea birds. The Pacific rat was another introduction, possibly as an unintended stowaway during the initial voyages of discovery, and it was later used as a foodstuff by some eastern Polynesian peoples. The early colonists also experimented with different fishing gear and angling techniques to catch both inshore reef fish and open-sea fish with fishhooks fashioned from bone and pearl shell.

Estimating population size can be difficult, but most accept that founding populations were small (in the range of 100–200 persons) and that most eastern Polynesian populations went through a logistical growth cycle up to and beyond 1000 CE. Typically one to two centuries

after initial colonization, the native food resources, especially land birds, had been depleted or made extinct through human predation. Thereafter bones of pig and dog appear with greater frequency at archaeological sites, indicating efforts to establish and intensify new subsistence resources that also included shifting cultivation. No archaeological evidence for *marae* (complex ceremonial sites) has been thus far recovered during the early settlement period, but linguistic reconstructions are suggestive that they developed at this time. Linguistic reconstructions also suggest that eastern Polynesian societies dating to this period were organized as chiefdoms, with hereditary rulers (chiefs) who inherited their positions based on their genealogy.

In many regions voyaging did not cease with initial colonization, although the remotest islands (Hawaii, New Zealand, and Easter Island) likely became isolated from exterior contacts soon after their settlement. Analysis of pottery and particularly adzes (axelike stone tools) has documented contact between central eastern Polynesian cultures and Fiji and Tonga. There is also widespread evidence that a complex regional interaction sphere in central eastern Polynesia linked the Societies, Tuamotus, and Marquesas, along with the Southern Cooks, Austral, and Mangareva-Pitcairn-Henderson, from perhaps as early as 900 CE.

A topic of long-standing interest in Polynesia has been the possibility of contacts with the Americas. Sweet potato, domesticated in South America, is now accepted as being imported into eastern Polynesia by 1000–1100 CE. This is based on the discovery and dating of carbonized sweet potato remains from sites in Mangaia (Cook Islands), Easter Island, and Hawaii.

The Settlement of Madagascar

Madagascar is an island that lies roughly 300 miles off the coast of East Africa. Like many large and reasonably remote islands, it is home to a remarkable flora and fauna, much of which is quite distinct from that of continental Africa. Thus instead of monkeys or apes, Madagascar has many species of lemurs. At the same time, it is still close enough to Africa that it also has species that have arrived from the African mainland, such as the Nile crocodile. Likewise, Madagascar's human population is partly derived from the African continent but also contains elements that are unlike anything else found in Africa.

Early visitors to Madagascar were struck by the appearance of the Malagasy (as both the people of Madagascar and the language they speak are called). The Malagasy did not look like or share the languages of the people who lived on the East African coast. They looked more like Indonesians. Modern linguistic and genetic studies confirm these earlier observations. Linguists have demonstrated that the closest living language to Malagasy is spoken on the island of Borneo. Recently, geneticists have shown that the population of Madagascar gets about half its genetic material from Africa and half from Southeast Asia. The Malagasy, it would seem, are the westernmost branch of the Austronesian expansion, the epic human migration that brought speakers of Austronesian languages to Southeast Asia as well as to many of the islands of the Pacific in the East and to Madagascar in the West.

The gradual Austronesian expansion into the Pacific is relatively easy to trace, but not so the route or even the timing of the migration that brought Austronesian speakers to Madagascar. Linguistic evidence suggests that the Malagasy arrived in Madagascar as far back as 2,000 years ago. Genetic evidence indicates that they arrived between 2,000 and 1,500 years ago. Genetic studies of the banana, a plant that is believed to have been introduced to Africa by the Malagasy, sug-

gest that it arrived at the beginning of the first millennium. Archaeologists, however, cannot find any evidence of human habitation there before the seventh century CE, so these early dates are not supported by any physical evidence.

What we can say is that at some time in the early centuries of the first millennium settlers from Southeast Asia came to Madagascar. Almost certainly they came by sea, although the route they took remains mysterious. Linguistic evidence suggests that there was more than one wave of settlers that came to Madagascar, indicating that the colonization process happened accidentally more than once or that word got back of the success of the first settlers. There are two ways that settlers might have reached Madagascar from Southeast Asia. They could have followed the northern arc of the ocean by way of India to the East African coast and then south to Madagascar. On some levels this seems most plausible. People who followed this route would have been able to get food and water on the way, a crucial consideration for people in open boats. However, there is neither archaeological nor linguistic evidence of their passage along this route, so if they did follow this route they did not tarry along the way. The other possibility is that settlers came to Madagascar accidentally, swept across the southern reaches of the Indian Ocean on the current that moves southwest toward Madagascar. But this would have meant months on the open sea and settlers who would probably have arrived half-dead. And surely this would have killed any living plants, such as banana seedlings, on board.

So no one is certain how the Malagasy got to Madagascar. We know only that they did. It speaks highly of the seafaring skills of the people who made these voyages, no matter which route they followed.

➤ WHAT DID THE MALAGASY BRING WITH THEM?

The epic migration of the Malagasy would be little more than a testament to human endurance were it not for the role they played in introducing a number of crops and, perhaps, technologies into Africa. Because the arrival in East Africa of bananas and varieties of yams and rice that were native to Southeast Asia coincides with the arrival of the Malagasy, they are usually given credit for bringing these crops to Africa. Southeast Asian yams and rice offered new varieties to African farmers who already had other varieties of both these crops, but bananas were something new and significant. Bananas were extremely productive, tolerated high rainfall, and once established required little labor. As such, they were an ideal crop for rain forest farmers who had struggled for a millennium to farm the high rainfall zones of central Africa. Bananas played a crucial role in increasing the population of the forest zones. It is also possible that the Malagasy introduced outrigger canoes and xylophone-like musical instruments to East Africa. Both of these are also found in Southeast Asia, but here the chain of transmission is unclear, and many scholars contend that these technologies were developed independently in Africa.

—Erik Gilbert

The Climax of the Bantu Expansion

The period 300–1000 CE was one of great transition in East, central, and southern Africa. In circa 300 CE Bantu-speaking peoples migrated into already settled regions. By 1000 CE Bantu-speaking peoples had moved from the Great Lakes in Uganda to the Cape Coast in South Africa. Not only had they thrived in these regions, but also they had Bantuized the vast majority of the original inhabitants. Today the vast majority of peoples of these regions speak 1 of over 800 Bantu languages.

It is still unclear how these matrilineal decentralized agriculturalists were able to have such a long-term impact on vast parts of Africa. One possible answer is that the Bantu-speaking immigrants had a very flexible approach to the peoples they encountered. They moved out of the rain forests with knowledge of yam cultivation

THE PEACEFUL PEOPLE DOMINATE

Politically centralized peoples with better technology will always dominate the decentralized, less technologically advanced, or so the historians claim. By 1000 CE Bantu-speaking peoples had moved from the Great Lakes in Uganda to the Cape Coast in South Africa. Not only had they thrived in these regions, but they had also Bantuized most of the earlier inhabitants, who in turn taught them iron smelting, grain cultivation, and animal husbandry (the important technological innovations of the era). Today in East, central, and southern Africa the majority of the peoples speak Bantu languages. How did these nonwarrior, matrilineal, decentralized peoples, who arrived in the region with only pottery technology and root agriculture, absorb all these technologically advanced people? This is the major question confronted by scholars who are currently studying the Bantu expansion.

—Christine Ahmed-Saidi

and goat herding, yet by 1000 CE they had become successful pastoralists and grain and banana farmers. As they moved into new ecological regions, they learned food-producing technologies from the peoples they encountered. These skills enabled them to survive in such diverse climates. By the fourth century CE diverse populations had settled East, central, and southern Africa.

Africa has four major language families, each dating back over 10,000 years. East Africa was the region where members of each of these language families met and often merged. Bantu languages are the daughters of the Niger Congo language family that was originally centered in West Africa. The Southern and Eastern Kushitic-speaking peoples lived in the northeast sections of East Africa and were part of the Afro-Asian language family, whose other languages include Berber, Hausa, Arabic, and Hebrew. The Southern Nilotes and the Central Sudanic peoples of the Nilo-Saharan language family resided in northwestern East Africa. The Kosians, a hunting and gathering people, lived in southern East Africa.

The language evidence indicates that Bantu-speaking peoples learned iron smelting, grain cultivation, and cattle raising from Central Sudanic-speaking peoples. They also acquired

knowledge about cattle raising and grain cultivation from the Kushitic-speaking peoples they encountered. The Indonesian immigrants, who most probably intermarried with some Bantu-speaking peoples, introduced bananas and other Asian crops. The Khoisan-speakers taught the Bantu-speaking peoples how to forage for extra food sources. Finally, the Batwa passed on fishing techniques to the Bantu-speaking peoples.

While these interactions were often reciprocal, the key element in understanding the success of Bantu speakers is found in their flexible approach. Since Bantu societies were matrilineal and thus limited by the number of children a clanswoman produced, they often recruited from outside peoples. Oral histories from later periods show that many intratribal quarrels within Bantu society led to one group moving on to a new territory and accommodating themselves to their new neighbors and new environs. These successful settlements laid the basis for the following historical period in which some Bantu-speaking peoples, but certainly not the majority, created centralized polities and began to dominate other peoples.

Arab Muslim Garrison Towns—Agents of Arabization and Islamization

With the foundation of the Islamic state in 622 in Medina, the first Arab/Muslim army struck out on some 80 raids against the city of Mecca,

eventually conquering it and most of the Arabian Peninsula. Muhammad's death in 632 inaugurated the era of the Rashidun (Rightly Guided) caliphs (632–661), and the second of these caliphs, Umar I (r. 634–644), oversaw the caliphate during its period of most rapid expansion. Launching campaigns against the Byzantine empire to the west and the Sassanian empire to the east, both of which were weakened after almost a century of conflict, the Arab armies directed the momentum gained from their new unity outward against the day's two greatest empires in western Eurasia. While the Arabs had often raided the border regions in the past, the idea of empire building was definitely new.

As Arab armies pushed out of the peninsula on these campaigns, they began to establish military centers in the newly opened territories. These garrison towns were known as *amsar* (sing., *misr*) and were located on the fringes between the desert and the settled land, near to preexisting urban areas. Cities such as Basrah and Kufah (both founded in Iraq in 638) and Fustat (known as Old Cairo and established in Egypt in 642), were the most successful of these garrison centers. Regions conquered by armies from a garrison center would be administered from and remit taxes to that *misr*. As the *amsar* became centers for the collection of taxes, they also became the seats for the regional governors.

According to Arab administrative practices during the Rashidun period, the caliphate was roughly divided into four administrative regions. Syria was administered from Damascus; the eastern caliphate was run from the *misr* of Basrah, Egypt; the West was administered from Fustat; and Arabia was governed from Medina. This corresponded to the major thrusts of the Islamic conquests and illustrated the growing importance of these frontier towns to the burgeoning Islamic empire. Indeed, Kufah was briefly the capital of the caliphate during the time of the fourth Rashidun caliph Ali b. Abu Talib (r. 656–661). Thus, these garrison cities were not only critical military centers but were also important administrative centers.

Under the Umayyad dynasty (661–750) expansion continued, but fiscal issues began to undermine the system. From the time of Umar I, soldiers were paid stipends (*ata*) from monies

Al-Kufa Mosque in Kufa, Iraq, seventh century CE. Kufa, the first of the Muslim garrison cities, served as the capital of the caliphate during the reign of Ali, and again in the early years of the Abbasid caliphate. (Art Directors.co.uk)

levied on conquered lands in their home *misr*. The amount that each soldier received was listed on a state registry (*diwan*) and was based on when the soldier joined the Islamic movement. Those who joined earliest received the most money. This system, based in part on existing practices among both the Byzantines and the Sassanians, worked well when the wealth produced from taxable land was high and the amount of soldiers drawing from the revenue was low. However, by the time of the caliph Abd al-Malik (685–705), many of those claiming *ata* were no longer a part of the military.

As military spending became increasingly tight the pace of demilitarization quickened, with soldiers choosing instead to raise families and ceasing their military service. However, the *ata* was considered to be heritable, passed from a father to his sons with each generation. Thus, it became painfully obvious that the demographic nature of the caliphate was changing. With the breakdown of the *amsar* system, the Arab military levies were increasingly dispersing into the native population, becoming almost indistinguishable from the conquered peoples.

The accumulation of wealth and power that these *amsar* created had another effect. These centers became desirable to the indigenous populations for the economic and political opportunities they afforded. Where capital accumulated, there was always the opportunity for trade, and

➤ KUFAN AND POLITICAL DISSENT IN THE EARLY ISLAMIC PERIOD

Located about 102 miles (170 kilometers) south of Baghdad and about 6 miles (10 kilometers) north-east of Najaf, the city of Kufah has played an important role in the early history of the Islamic world. It was founded as a military encampment, *misr*, on the Euphrates River near the city of Hira in 638 by Said b. Abu Waqqas (584–664), an early convert to Islam and companion of the Prophet Muhammad (570–632). The city stood at the edge of the desert and the rich alluvial lands between the Tigris and Euphrates rivers known as the *sawad* (black lands). However, the tribal levies housed in Kufah were not allowed to possess the *sawad* lands, leading to discontent among the soldiers stationed there. Military setbacks and a truculent attitude toward the governor appointed by Caliph Uthman I (r. 644–656) led to a diminished status for the city.

Upon the death of Uthman, the city fell fully into the camp of the last Rashidun caliph, Ali b. Abu Talib (r. 656–661), who supported the economic and social grievances of the population. It briefly served as Ali's capital and continued their support of his family after Ali's assassination. It was to Kufa that Husayn (626–680) was fleeing during the reign of Yazid I (680–683). Husayn hoped to use the support of the population to launch his revolution against the Umayyads. However, Husayn was killed at Karbala in 680, effectively ending the claim of Ali's lineage to the title of caliph but also creating the crystallizing moment of Shia opposition to the Umayyads. Thereafter, Kufa remained a city with deep Shia loyalties, becoming a center for rebellion, such as the revolt under Mukhtar (622–687), and the articulation of Shia theological doctrine during the late Umayyad (661–750) and Abbasid (750–1258) periods.

—*Rasheed Hosein*

trade flourished from these centers. Also, because these *amsar* were burgeoning administrative centers, there was a great demand for administrative and clerical officials to aid in the governance of the regions. This encouraged the Arabization of the native population, as trade and governance were both conducted in Arabic by this time. Indeed, classical Arabic grammar was classified into two schools, the Kufan school

and the Basran school, after the grammarians who taught Arabic in each of these *amsar*. Thus, these centers caused the conquered populations to gravitate toward them, established Arabic outside the Arabian Peninsula, and helped the conquered to forge commercial and personal ties with the Arab elite therein.

This demographic movement and general demilitarization created unique fiscal problems for Abd al-Malik. With the pace of conquest slowing, the caliphate increasingly relied on taxation to fund the state. At the moment of conquest, two taxes were generally levied on the newly conquered lands. The *kharaj* (land tax) was assessed on land seized by force, and the *jizya* (head tax) was applied to all inhabitants who did not convert to Islam. While rates for both the *kharaj* and the *jizya* fluctuated from region to region, the sources note that the amount a non-Muslim paid to the caliphate in taxes was greater than the taxation amount paid by Muslims (known generally as *ushr*). Thus, despite the fiscal benefits available with Islam, it was often in the best interests of provincial administrators to discourage active conversion because of the possible fiscal strain to the state.

These two trends thus converged at the start of the eighth century to fundamentally alter the nature of the caliphate. As soldiers dispersed, they traded with and married into the indigenous populations moving into the *amsar*, speeding up the Arabization and causing the Islamization of the conquered territories. This created unique questions surrounding the issue of classifying one's status for Abd al-Malik and the later Umayyad caliphs.

For Arabs descended from the original conquest levies, did they still qualify to receive *ata*? Did converted peoples, even those married into Arab families, qualify for the *ushr*, or were they to pay the *jizya*? Abd al-Malik and his successors sought to maximize the revenues for the state while maintaining the status quo where they could. The issue of military pay was addressed, with the *diwans* updated to remove people not in service. However, the *mawali* (sing., *mawla*, in this context meaning non-Arab converts to Islam) maintained a higher level of taxation. This created two tiers of believers in the Muslim community, the Arab Mus-

lim and the non-Arab *mawla*, that led to great disaffection in these *amsar*. In 750 the Abbassids, tying into this current of unrest, launched their revolution from the Eastern caliphate, overthrowing the Umayyads and establishing the Abbasid dynasty (750–1258).

Arab Diaspora—The Special Case of Spain

Although a vibrant and rich Arabo-Islamic culture emerged in Al-Andalus (Muslim Spain, or Iberia), Arab emigration was minimal at the time of conquest and negligible in future years. Amazigh (Berber) peoples came in larger numbers, but the overwhelming majority of the population in Al-Andalus was indigenous.

In 711 CE the commander Tariq ibn Ziyad crossed to Al-Andalus with an invasion force of approximately 12,000 soldiers along with their families. These included a core of Arab officers, whereas the bulk of the army was made up of Amazigh tribesmen and included some central African slaves. In the initial battle with the Visigoths there were some 3,000 Muslim casualties. The following year Tariq's superior Musa b. Nusayr arrived with 18,000 soldiers, among them many Arabs of the Yamani tribes and distinguished members of the Quraysh. These early settlers (known as *baladiyyun*) dispersed throughout the crumbling Visigothic kingdom, including Spain and Languedoc. The Amazigh settled mountainous areas that recalled their native lands. Soon after the conquest they were

➤ BALJ B. BISHR—THE LIFE AND DEEDS OF AN ARAB IMMIGRANT

The Arab Balj b. Bishr came to the Muslim West along with his uncle, Kultum, leading Syrian troops who had been sent to quell a large-scale Berber revolt in the Maghreb in 740 CE. When Kultum was killed Balj took command of the force, which numbered perhaps 8,000 Arabs and 2,000 converted clients along with their families. Balj soon found himself hemmed in at Ceuta while the revolt spread to al-Andalus in 741. Unable to contain the rebels there, the governor Ibn Qatan invited Balj to aid him, providing transport from Africa on the condition that Balj return to Morocco after quelling the rebellion. But after routing the Berber forces near Algeciras, Balj marched on Cordoba and had Ibn Qatan imprisoned and executed. Balj's troops were then given choice lands in southern Spain to settle and were exempted from taxes, which exacerbated tensions with settlers of the previous generation and touched off further fighting in which Berbers joined with Arab factions loyal to the executed governor against Balj and other Arab settlers who supported him. The tribal aspect that historians have traditionally attributed to this struggle has probably been exaggerated. Balj's arrival represents the last significant settlement of Arabs in Iberia.

—*Brian A. Catlos*

marginalized by the Arabs, provoking a region-wide revolt that began in 739.

As a consequence, the commander Balj b. Bishr and his predominantly Syrian Arab (*shamiyyun*) force of 10,000 were invited to come to Spain to crush the revolt. After defeating the rebels, Balj staged a coup. Seizing choice lands and claiming tax exemptions, the *shamiyyun* provoked the *baladiyyun* and early Amazigh settlers into a civil war. Often portrayed as a struggle between Yamani and Qaysi Arab tribal federations, in fact it was one between settlers and newcomers. This war dragged on until the arrival in 757 of the Umayyad refugee 'Abd al-Rahman, who imposed his authority by bringing in his own Amazigh troops to sap the power of the Arab settlers.

In the 800s the indigenous population converted overwhelmingly to Islam and along with the Amazigh integrated into Arabo-Islamic culture. Early converts became clients (*muwalladun*) of Arab families and appropriated their genealogies and privileges. But the *muwallad* elite soon chafed against Arab domination, and this provoked a series of revolts through the ninth century and manifestations of anti-Arabism as a cultural phenomenon. By the reign of 'Abd al-Rahman III (912–961) these questions had largely been settled; a core Arab elite remained a powerful faction, but for all intents and purposes integration had led a new Andalusí ethnicity to emerge. However, under 'Abd al-Rahman III and his successors, new Amazigh settlers were brought in to serve in the army and undermine the native military elite. As these culturally distinct foreigners gained power and prestige, tensions with the Arab elite and the Andalusí populace grew, culminating in a popular uprising and massacre at Córdoba in 1031 as the caliphate itself disintegrated. Subsequently Muslim Spain would be conquered by two North African factions, the Almoravids (late eleventh century) and the Almohads (twelfth century), and Christian Spain would be subject to inconclusive invasions by the Marinids (late fourteenth and early fifteenth centuries), but settlement and colonization were not significant during these episodes.

The net result of the light Arab and Berber immigration to Spain was that although local Romano-Visigothic culture was nearly eradicated, an extremely fecund Islamic culture developed in its place, which in turn provoked monumental transformations in Jewish culture and that of the Latin West.

Arabization and Islamic Conversion of the Middle East and North Africa

The Arab Muslim conquest of an empire stretching from Spain to the Ferghana Valley in central Asia was extremely rapid, requiring little more than a century, but the spread of the Arabic language and the conversion to Islam of a majority of the population in this vast area were much slower, requiring many centuries.

The spread of culture and all that entails in terms of religion and language is a process not neatly marked by dates of battles and time boundaries of ruling dynasties. It took longer for Christianity to become the dominant religion in the Roman empire than the span of time from the American Revolution to the present. Christianity was still struggling for converts on the fringes of Europe in the tenth century CE at the time that Islam was finally becoming the majority religion in territories controlled by Arab dynasties. Conversion to religion and adoption of language are complex processes that do not automatically follow military and political domination.

The first peoples brought under Muslim Arab control outside the Arabian Peninsula were in the Fertile Crescent and Nile Valley, ruled by the Byzantine and Sassanid empires. The Arabic language gradually became the major language of the region. In the first generations, the Arab conquerors governed through Byzantine and Persian administrators, and Greek and Persian were the languages of government. It was not until late in the seventh century that Arabic became the language of government. Islam gained many adherents and is the majority religion today, but that took longer than the spread of the language. Both the Byzantine and Sassanid empires sponsored Arab tribes at the edge of the peninsula, the Lakhmids and Ghassanids, as a buffer between their empires and the Arab tribes of the Arabian Peninsula. They spoke Arabic, had trading ties with the Hijaz, and had long been exposed to the monotheistic religions of Judaism and Christianity and the nonpolytheistic religion of Zoroastrianism. As the Muslim Arab empire expanded, encountered peoples spoke Aramaic as their common language and were Christian or Jews of both empires. The

Jews were minorities in both empires, and many of the Christians were considered heretical sects by the Byzantine Christians. Acceptance of Arab rule was not a problem, nor was adoption of Arabic. Conversion was, however, a slow process.

A feature of early Arab conquests may help explain why these did not lead to massive conversions even as Arab rule expanded so rapidly. The first Arab armies followed a policy of separating themselves from conquered peoples by establishing military bases to house armies for further conquest. These included Kufa and Basra in lower Mesopotamia and Fustat on the Nile. All three were on the edge of the desert with major rivers behind them, easing communication over desert routes to the Hijaz and providing easy routes for conquest via river routes. Kufa was west of the Euphrates and Basra west and south of the Shatt-al-Arab below the junction of the Euphrates and Tigris rivers. Fustat was east of the Nile, near present-day Cairo. All three had caravan routes to Mecca and Medina with no major barriers intervening. All three aided advance via the rivers to the rest of the Fertile Crescent and Nile Valley. For the first years the Arab armies contented themselves in these military camps by capitulation settlements with conquered territories and the collection of the Jizyah.

This separation broke down as these military camps became more permanent, attracting peninsula Arabs for prospects of trade and for migration of the families of the conquering armies. Conversion of native peoples for reasons of economic and social advance began, although slowly. Some of the conquered people became clients (*mawali*) of Arab tribes. This provided a route to Arabization and Islamization. The practice of polygamy by Arab tribes was also a factor. Islam limited the number of wives to four, with all having equal rights under Sharia (Islamic law). Moreover, wives did not have to convert, able to retain their previous beliefs, while Muslim females had to marry only Muslim males. Intuitively, it is likely that non-Muslim wives may have encouraged sons to become Muslim for social and political advancement.

Cultural and religious expansion depends on many factors, and these help explain how and how long it took for the Fertile Crescent to become Arab and Muslim. Foremost was the fact

that the populations of the region spoke Semitic languages, and many resented domination by the two dominant empires. Rule by Arabs and adoption of that Semitic language were not problems. Rule by monotheistic Muslims was easily accepted by monotheist Jews, Christians, and dualistic Zoroastrians, as Islam recognized their religions as "Peoples of the Book," although their books were deemed flawed. For Jews and many Christians second-class citizenship in the Arab empire, being subject to the Jizyah, or poll tax, and other restrictions were less a burden than persecution by the Byzantine or Sassanid rulers of the time. They had the legal status of *dhimmi*, protected people who were subject to their own religious leaders for legal matters regarding marriage, inheritance, contracts, and other matters now considered part of modern civil law.

The early expansion of Muslim rule did lead to some conversions to Islam, as this exempted converts from the Jizyah and was perceived as a way to advance in social and political status under the new regime. The Arab tribes expanding into the Fertile Crescent and Nile Valley developed the concept of Mawla (pl. Mawali), which allowed converts to become adopted members of the tribes. This and the tax exemptions led to the first wave of converts. It seems to have been especially attractive to non-Semitic speakers of the Sassanid empire, who could become Mawali without changing their language from the Indo-European Persian or Kurdish. This may help explain why the Persian-speaking part of the Arab conquest actually preceded the Semitic portions in the proportion of conversions. Iran retains its ancient language but is overwhelmingly Muslim. This may reflect the failure of Arabic to become the common language of Muslim countries outside the Fertile Crescent and Nile Valley, which now far outnumber Arabic-speaking Muslims.

Richard Bulliet has studied this in detail, based on examination of the prevalence of Muslim names in biography compilations and a lifetime studying the Middle East. It appears that there were two peaks in adoption of Islamic names. The time line depended on place, the first peaks occurring in areas first subjugated by Arab-Muslim forces and somewhat later as Muslim conquests expanded. That occurred two centuries later. The first peaks did not indicate a

massive conversion to Islam; as an example, less than 10 percent of the names in Iraq and Syria were Muslim by the end of the Umayyad dynasty in 750 CE. A simple majority of Muslim names did not occur until a century later. Overwhelming majorities waited until the tenth century, roughly the same time that Christianity expanded into Russia. This is consistent with the long process involved in cultural expansions of the past. That contrasts with the phenomenon of the dispersion of American popular culture: blue jeans, T-shirts, and sports caps over the past 50 years. The essence of American—or more widely understood West European—culture is not reflected in such visual images. It should not be surprising that the essence of Arab culture and Islam took time to develop.

Migrations in the Americas

Migrations are defined as the permanent resettlement of a large number of people from one territory to another. This process includes their cultural and technological heritage. Migrations in the Americas are considered one of the key methods by which ideas, art styles, weapons, and domesticated plants have spread from their points of origin to other regions.

Scholars generally accept that the appearance of humans in the Americas is the result of migration from Asia. It appears likely that groups

of hunter-gatherers from Asia appeared in Alaska and the Pacific Northwest thousands of years ago and gradually migrated throughout both continents. They probably followed the animals they hunted and searched for more hospitable environments. For most of humans' early presence in the Americas, the population density was quite low. If a group of people found that a location was undesirable either because of environment or unpleasant neighbors, it was simpler to move to another location.

The development of agriculture and dependence on domesticated plants as the major sources of food ended wandering. Fertile regions for growing plants like squash and maize were desirable and not present everywhere. Migrating groups might displace those who were already in place as different groups competed for the same resources, or they might conquer the territory and establish themselves as elites who ruled the population.

The causes of migrations usually fell into a few categories. One of the most common was environmental disaster or decline. In the classic era of Mesoamerica (250–900 CE), a severe drought forced many farming peoples who lived along the northern borders to search for new lands to the south. These migratory groups pressured the existing states and contributed to the decline of Teotihuacan during the seventh century CE. A common ecological cause was the declining fertility of land. Some archaeologists have proposed that the Mound Builders of the Mississippi were dispersed because their maize-growing farmland could no longer produce sufficient crops. Another common cause of migrations was to escape the exploitation by other groups.

Migrations can be traced over the centuries by linguistic characteristics of Native American languages. Related languages and their degree of similarities indicate the origins of the speakers and how long ago the groups may have separated. One example would be the close relationship between the Athapaskan peoples of Alaska and the Apaches and Navajos of the American Southwest.

Other indications of significant migration are architectural styles and other nonmovable artifacts that suddenly appear in a location after

a certain date. Some significant indicators of migrations include cultural practices such as similar deities that are worshipped in different locations, such as Quetzalcoatl. Other examples of cultural diffusion through migrations in Mesoamerica are I-shaped ball courts and skull racks. Human sacrifices and the religious significance of green obsidian are others.

Migration in the Americas was a constant process between 300 and 1000 CE. Groups of Athapascan people migrated from Alaska to the American Southwest, where they became the Navajo and Apache tribes. The Arawak may have originated in the Andes and spread along the river valleys of Amazonia, where they became the most important group of inhabitants. Those peoples who did not migrate during this time were the exceptions to the rule.

Controversy—Migration or Autochthonous Development?

The presence of ideas, art styles, religious practices, and plants in different regions of the Americas has caused difficulties for archaeologists and historians. They have debated whether similar styles and practices spread from one central point of origin or whether styles and practices developed at different times and places among multiple groups in response to similar environmental conditions.

For many years anthropologists and archaeologists believed that the most likely explanation for why these elements appeared in different cultures throughout the Americas was because of migration or diffusion. Migration indicated that a sizable proportion of a population moved from one place to another. In such a migration they brought along their cultural characteristics, such as ideas about art and religion. They also brought plants that they grew and goods such as pottery. The reasons for migrations might include a search for better land and resources, the desire to be free from rule by another group, or greater religious freedom. The most famous example may be the Aztecs, who migrated to the Basin of Mexico from an unknown location to the northwest. After being

➤ DID THE EXAMPLE OF MESOAMERICAN PYRAMIDS STIMULATE MOUND CONSTRUCTION TO NATIVE AMERICAN CULTURES?

The Mound Builders' mounds and the Mayan pyramids had similar shapes and were both used for religious functions, leading many to originally believe that they were the result of migration from Mesoamerica to the Mississippi River valley. Today, however, most archaeologists believe that the groups had no contact and that the similar structures arose because of similar needs.

—Timothy J. Watts

Despite the similarities between the pyramid at the Cahokia Mounds settlement in present-day Illinois (depicted at its height, left) and the Pyramid of Kukulcan at Chichén Itzá in present-day Mexico, archaeologists believe the two groups arrived at their shapes without any direct contact. Similar requirements probably led to similar architectural styles. (Cahokia Mounds State Historic Site, painting by Michael Hampshire)

dominated and forced to move by other groups, the Aztecs founded their own state and eventually controlled all the peoples in the Basin of Mexico. These reasons have been shared by humans who migrated in all parts of the world. In many parts of the Americas migration was a peaceful process if population density was low. Most peoples found it easier to relocate than to fight. Migration sometimes included violent conquest, such as the movement of the Olmeca-Xicalanca from the Gulf of Mexico coast into the Mayan highlands around 900 CE. The Olmeca-Xicalanca established their authority over the autochthonous, or indigenous, population and ruled as an elite.

Even if violent, the migration of one people into another area resulted in a blending of cultures that gave rise to a more sophisticated one. Archaeologists recognize this change when architecture, art, and other aspects change radically in a culture with little advance signs. One example is from the Toltec state, centered at Tula. Around 900 CE the Nonoalcas migrated to Tula and joined with the Chichimecs from northern Mesoamerica. The two cultures created a dynamic hybrid that made the Toltec the dominant state in Mesoamerica for two centuries.

Diffusion is a mechanism related to migration for the spread of culture. In diffusion, small groups from one culture carry information and examples of goods to another group, sometimes over long distances. In the Americas, traders and merchants were the prime examples of this factor. Diffusion is ordinarily a peaceful process. Through diffusion, new types of artwork, pottery, and religious rituals might make their appearances in other cultures. Most often, diffusion is responsible for only a few new characteristics in a culture. Diffusion is sometime cited as the agent in the spread of domesticated species such as maize, beans, and squash from Mesoamerica to North America.

Autochthonous development has gained more prominence among archaeologists in the past three decades. They have been more interested in considering how environmental factors can affect a peoples' development. Under this theory, similar characteristics may appear in widely separated locations in response to similar stimuli. These characteristics may not be as sim-

ilar as observers at first assume, however. Similarities between pyramids in Egypt and those in Mesoamerica are limited, since both were used for different purposes. Likewise, the mounds built by the Mississippi Mound Builders beginning around 900 CE were believed to have been inspired by pyramids in Mesoamerica for many years. Archaeological evidence, however, indicates that the first mounds in the Mississippi Valley predated contact between the two civilizations and had less of a similarity than was believed. Authorities now believe that cultures faced with similar conditions are likely to come up with similar answers.

Transpolar Movement of Inuit—The Thule Tradition

The Inuit managed to survive and even thrive in one of the harshest climates on earth. Their migration across the Arctic from Alaska to Greenland resulted from a search for better hunting, especially of marine mammals such as seals and beluga whales. Their superior technology allowed the Inuit to displace or assimilate the people of the Dorset culture who had settled in those regions before them.

The Inuit share cultural and ethnic ties with native peoples of Siberia. They probably crossed into North America during the Late Ice Age. Their original home was in northwestern Alaska, where they developed technology to hunt whales, seals, walrus, and other marine mammals as their main source of food. Arctic archaeologists believe that the Thule Inuit began to migrate eastward in the later half of the first millennium CE, although some recent excavations

indicate that their migration may have commenced centuries later than first thought. It is believed that the climatic warming associated with the Medieval Warm Period (ca. 800–1300 CE) brought bowhead whales into the Arctic Ocean, and the Inuit traveled along the coast in pursuit. They moved in small groups, probably consisting of members of an extended family. When they reached Baffin and Somerset islands, the Inuit constructed whaling villages, thought to have housed 50 to 100 people. They used driftwood and whale bones as the framework for houses. Thick pieces of sod provided insulating walls for their multifamily dwellings. These houses were extremely small by modern standards, scarcely more than eight by ten feet (two by three meters), and were rounded or oval in shape and sunk into the surrounding ground. The entry would be excavated even lower than the living floor to provide an air lock for the warmer interior of the dwelling. The inhabitants slept on shelves covered with slabs of rock, rushes, and other vegetation and, finally, skins and furs. Permanent settlements were used mostly in winter.

During the summer months, the Inuit broke into smaller groups to follow herds of caribou and musk ox.

Inuit technology was better suited to life in the Arctic than the Dorset people, whom they displaced. The Inuit were masters of using bones and other animal products to create advanced harpoons, bows and arrows, clothing, and other necessities. They traveled with dogs and dogsleds, kayaks, and seagoing umiaks, constructed on a design that was superior to that of their Dorset predecessors. Their ability to pursue and kill large mammals like whales provided them with a better standard of living than other peoples, since only one whale could support a village for some time.

The Thule eventually, perhaps after 1000 CE, reached Greenland, where they met the Norsemen who had settled southwestern coast in the tenth century. By about 1200 CE, Thule Inuit made contact, usually hostile, with the Norse colonists and may have been a factor in the collapse of the Norse settlements.

Movement of Teotihuacan into the Maya Highlands

One of the more expansive civilizations of Mesoamerica was that of Teotihuacan, whose influence at its apex extended to the far north of Mexico and as far south as Guatemala. The site of the great city of Teotihuacan (referred to as “the place where gods reside” by the Aztecs) is about 30 miles northeast of modern-day Mexico City. People began to inhabit this location by about 200 BCE, and at its height it was the center of a vast trading empire that exchanged goods with nearly all the Classic Period peoples

of Mesoamerica. As of 300 CE Teotihuacan was a fully developed civilization, whereas that of the Maya was just beginning to evolve as a great Mesoamerican culture in its own right.

Many archaeologists suggest that the decline of the Maya highlands communities (such as Abaj Takalik, El Baúl, and Kaminaljuyú as well as others) emanated from intrusions by Teotihuacanos. By about 400 CE a massive influx of people from Teotihuacan led to a gradual decline of the culture and civilization existing in the Maya highlands. Many who have studied this process assert that it occurred either as a consequence of invasion or massive migration of the Teotihuacanos to the highlands. An illustration of this development is the Maya highland community of Kaminaljuyú, which over the course of the two centuries after 400 CE witnessed its nearly complete reconstruction according to the architectural style of Teotihuacan. This evolutionary pattern essentially ended the political and economic autonomy of Kaminaljuyú. Other evidence of the growing influence of Teotihuacan over this city is the pottery found by archaeolo-

gists within its tombs that show a distinct Teotihuacan origin or influence. If it is the latter, it would appear that the local artisans adopted the style reflecting the dominance of the central Mexican city-state perhaps because of the direct intrusion and immigration of the Teotihuacanos. In particular, the pottery unearthed by scholars to a large extent contains images of the gods worshipped by Teotihuacanos and their elites, bedecked in their full regalia. It is certain, given the evidence and artifacts, that most of the Maya highland communities came under the domination of these invaders. The pattern of social, political, religious, and economic life was completely transformed within the highlands. Yet the Maya were able to hold on to many of their spiritual values and beliefs. To the present-day the indigenous people of Guatemala, Honduras, southern Mexico, and El Salvador cling to their divination through their shamans, sometimes referred to as “the keepers of time.”

The influence of Teotihuacan was not confined entirely to the Maya highlands. Within the lowlands these influences had spread as of the fifth century CE. Archaeologists have determined through their thorough excavations that this influence was especially prevalent in Tikal. Funerary objects show a definite connection to the styles of Teotihuacan. (Of note are murals depicting warriors of Teotihuacan as attendants to the deceased rulers of Tikal.) Another rationale besides the intrusions from Teotihuacan explaining the Maya highlands demise revolves around the the devastating volcano eruptions of Ilopango between 200 and 250 CE. All of the communities of the Maya highlands saw a protracted decline in their economies, which were so dependent upon their extensive trading networks.

Southward Migration of Athapascans

The Athapascans (sometimes spelled Athabascans) were probably the last group of people to migrate from Asia into North America. They originally settled in eastern Alaska and northwestern Canada. Tribes such as the Tlingit are subfamilies of the Athapaskan. Archaeological and linguistic evidence indicates that around 100 CE, some groups of Athapaskan began a migration to the south. While some groups ended up in the Pacific Northwest, others continued their migration into the American Southwest. The migration probably took the form of autonomous small groups drifting southward, looking for better hunting and greater safety. Most Athapaskan groups traveled through the eastern foothills of the Rocky Mountains, although some used the route through the Great Basin. The migration continued for over 1,000 years, but the Athapaskan retained their unique language and cultural ways. Linguists discovered that speakers from Alaska and the Southwest could understand each other. Unlike other Native American languages, Athapaskan is tonal. Words with the same phonemes have different meanings according to their tones.

The Athapaskan followed a hunting and gathering lifestyle for most of their existence. Their camps during their migration consisted of conical structures with wooden pole frameworks that were covered with brush or hides. These early tepees could easily be taken down when needed, and most materials could be located at the next campsite. The Athapaskan also borrowed technology from the people they encountered on their migration, including the construction of stone walls without the use of any mortar. After arriving in the Southwest, groups of Athapaskan adopted much of the technology of the Pueblos.

One group of Athapaskan adopted the Pueblo way of life and became farmers around 1350 CE. Although they called themselves Na Dene (“The People”), they became known to the Spanish as the Navajo. Later arriving groups in Texas became the Apaches and retained more of a nomadic life. They were among the first Native Americans to adopt a horse culture.

Arawak Dispersal in Amazonia

Of all the many languages and ethnic groups in Amazonia, those based upon the Arawak family are the most numerous and widespread. It is believed by anthropologists that the Arawaks origi-

nated on the banks of the upper Rio Negro River and migrated throughout Amazonia by following the Orinoco and Amazon rivers and their tributaries. These migrations may have begun around 2000 BCE and certainly by 500 BCE. Arawak influences, known as the Arawak phenomenon, have been identified throughout the region, along its rivers, by anthropologists. While most of the region is covered by rain forests known for their poor soil, many of the floodplains along the rivers are quite fertile and suitable to intensive agriculture. Archaeological evidence indicates that the Arawak built habitation mounds for autonomous villages that rose above the seasonal flooding. Arawak migration may be traced by their characteristic pottery style and the cultivation of manioc as a staple food. The Arawak may

have been the first people to discover how to prepare manioc safely and to remove its natural poison.

One of the factors that made the spread of the Arawak so successful was their cultural emphasis on trade and cooperation. Although their villages were autonomous, the Arawak recognized their ethnic connections and sought to include groups into their culture. As a result, the Arawak were probably the most powerful and expansive people in Amazonia during 300–1000 CE.

While the Arawak successfully settled throughout Amazonia, they also migrated to the islands of the Caribbean during 500–1000 CE.

Their knowledge of watercraft because of experience on the rivers enabled them to voyage across open seas to places such as Cuba, Hispaniola, and Puerto Rico. The Arawak who colonized the islands eventually forgot their Amazonian origins and adopted a myth of originating in a cave on Hispaniola. They continued to trade with their relatives on the American mainland.

■ Introduction: Trade Diasporas

Throughout the early medieval age (300–1000 CE), long-distance trade took place in both the Eastern and Western Hemispheres (but not significantly between hemispheres). Merchants who engaged in this long-distance trade often settled for a season or permanently in trading cities far from their home country, leaving diasporas of their fellow countrymen in these ports and trading posts along the trade routes and transplanting familiar institutions and ways of behavior in these strange locales.

In the Americas, much-frequented long-distance trade routes were those provided by the great river systems, particularly the Mississippi-Missouri. Although artifactual evidence of this trade is not rare, it is difficult to make inferences about trade diasporas that it can be assumed to have existed.

In Afro-Eurasia, we have literary as well as artifactual evidence. Merchants and others who traveled the Silk Roads, for example, settled in diasporic communities from the Mediterranean to China. Sogdians, Parthians, Radhanite Jews, Buddhists, Manicheans, and Nestorian Christians all lived in diasporic enclaves, stopping in monasteries and caravanserais, introducing the culture of their native lands, and, in turn, assimilating and transmitting to their home countries some of the culture of their host communities.

Ports on the Indian Ocean littoral were also liberally seeded with trade diasporas. From East Africa to the Malabar Coast of western India, Romans, Greeks, Ethiopians, Arabs, Jews, “Syrian” Christians, Persians, and Indian Muslims jostled each other and established enclaves. And from India’s Cape Comorin to the Bay of Bengal and around the Malay Peninsula to teeming ports on coastal southern China, Malays, Chams, Indians, Persians, and Arabs traded and settled.

A similar situation obtained in the desert ports of the trans-Saharan trading system. Berber merchants settled in towns on the southern edge of the great desert, bringing Mediterranean goods and the Islamic religion.

These trade diasporas played a crucial role in increasing knowledge of the wide world in all places they tarried, but not without costs. In a savage antiforeign paroxysm, Chinese rebels sacked the foreigners’ quarters and slaughtered many thousands of Persians and Arabs.

Trade Diasporas on the Overland Silk Roads

The Silk Roads encompassed a network of overland routes that criss-crossed the Eurasian continent connecting China with the West. The routes were often dangerous and difficult. Traveling from one end of the Silk Roads to the other could take more than a year. For that reason, individual merchants seldom traveled the entire length but tended to trade between particular cities and/or outposts. Goods moved in stages, changing hands many times before reaching their destinations. Communities of Chinese, central Asian, and Western merchants developed in principal cities and towns along the way, serving

as trade facilitators, bankers, government officials, and provisioners and essentially providing infrastructures for fellow merchants, helping to ensure a continued flow of goods.

The Sogdians, an Indo-Iranian group, controlled the central Asian section of the Silk Roads and thus the trade itself from the second century BCE to the tenth century CE. By the eighth century members of the Sogdian diaspora were active in civic life in major central Asian and Chinese cities. Some were even awarded Chinese titles for their service. Gradually, many Sogdians abandoned long-distance trade, becoming agriculturalists or trading more locally. Sogdian research is still in its infancy, but current studies are beginning to reveal

➤ A FASHION FOR THE FOREIGN

During the Tang dynasty, China was unusually open to foreign ideas. Silk Roads trade and the presence of large numbers of foreigners helped create a fashion for the exotic. Foreign items of clothing, including the Western *hufu* (barbarian robe), a cross-fronted garment that fastened at the neck, were popular for both men and women. Central Asian hairstyles, hats, and shoes were adopted by the Chinese elite for informal wear. Musical performers and instruments from central Asia, such as the transverse flute and the *pi'pa*, helped transform Chinese music. Foreign dances, including the Sogdian swirl where the dancer twirled wildly on a small round mat were adopted by Chinese performers. Even members of the Tang elite, including Yang Gui-fei and General An Lushan, were said to have learned the dance. Foreign games were also imported, including polo. Developed in Persia, polo became a popular game for both men and women. Even household furnishings were affected. The Chinese gave up sitting on floor mats or pillows and switched to chairs, an import from central Asia that the Chinese called barbarian beds. Fruits and vegetables from the West, including pomegranates, and melons were added to the Chinese diet. Their names often begin with the word “barbarian.”

more about these merchants and the processes of Silk Roads trade.

More is known about Chinese merchants and trade diasporas in China because of the variety and large number of Chinese sources. Despite the fact that merchanting and trade were considered lower-class activities in China, many Chinese were involved in them. They also formed diaspora communities along the western Silk Roads. Some were centered around frontier military outposts established to prevent robbers from harassing merchants and stealing cargo, while others were created in cities of central Asia. A fresco of a Chinese merchant and his wife dating from the eighth century has been found in Samarkand, once the capital of the Sogdian empire.

Some of the most important diaspora communities were located in China's major cities, where they secured goods to be shipped westward. The Tang dynasty's primary capital, Chang'an, had a large foreign community that included Turks, Uighurs, Sogdians, Tocharians, Arabs, and Indians in its western quarter. They brought their faiths with them and built religious structures and monuments representing Nestorian Christianity, Islam, and Zoroastrianism, among others. Louyang, the Tang's second capital, also had a large foreign population, as did the city of Yangzhou, where several thousand Persian and Arab merchants did business at the intersection of Grand Canal and the Yangzi River.

The Chinese were ambivalent about foreign merchants, often subjecting them to restrictive laws and local animosity. In Chang'an the Office of the Caravan Leader monitored the affairs of foreign merchants and promoted trade. However, foreigners who died in China forfeited all their belongings and holdings in the country to the government, and those who married Chinese women were forbidden to leave. At times the foreign communities became targets of violence. In the eighth century thousands of Persian and Arab merchants were massacred in Yangzhou. Despite the dangers and restrictions, the chance to profit from the silk trade ensured that foreign merchants would continue to live and work in China as long as the Chinese government allowed them to do so.

Trade Diasporas on the Indian Ocean Littoral

The great distances to be covered by navigators on the Indian Ocean combined with the seasonal nature of the monsoon winds obliged traveling merchants to remain in foreign ports for months between voyages. Eventually, some merchants began remaining in foreign places to act as intermediaries between their countrymen and the people whose lands they now inhabited. Those who did not assimilate into the general population formed expatriate communities, either by bringing their own families to join them or by intermarrying locally. The descendants of these mixed unions developed distinct cultural identities and served as a bridge between the nations of their maternal and paternal ancestors.

There is considerable archaeological and written evidence for the existence of overseas communities around the Indian Ocean in the early first millennium CE. Tamil, Prakrit, and Old Sinhala inscriptions show that merchants from Sri Lanka, India, and Bengal sojourned in various places around the Bay of Bengal, and there were well-established communities of southern Arabian and Zoroastrian Persian merchants in southern India and Sri Lanka by the fourth century. Omani merchants were settled on the coast of Persia and were active in East Africa north of the Horn of Africa before the seventh century.

The coming of Islam represents a watershed in the commercial history of the Indian Ocean. Zoroastrian merchant exiles fled the Persian Gulf to settle in India, Sri Lanka, and East Africa, but converts to Islam followed in their wake. By the eighth century, Persian, Arabian, and Omani Muslims had established themselves on coastal islands including the Lamu archipelago, Zanzibar, Kilwa, and Shanga. In the same period they

➤ MUSLIM VIEWS OF HINDUS IN THE TENTH CENTURY CE

After the eighth century, the rise of conservative Brahmanism made India increasingly dependent on non-Hindu traders. A tenth-century Muslim noted the complex and expensive rituals associated with eating: “There are certain Indians, who never eat two out of the same dish, or upon the same table, and would deem it a very great sin if they should. When they come to Siraf [in Persia], and are invited by the considerable merchants, [whether they are] a hundred in number, or more or less, they must each have a separate dish, with the least communication with the rest.”

Abu Zayd Hasan ibn Yazid Sirafi, “Concerning the Voyage to the Indies and China,” in *Ancient Accounts of India and China by Two Mohammedan Travellers, Who Went to Those Parts in the 9th Century*, translated by Eusebius Renaudot (1733; amended reprint, New Delhi: Asian Education Services, 1995), 98–99.

also settled the Comoros Islands, which lay astride the monsoon sailing route from southern Mozambique to the Persian Gulf.

Some of the Muslim trading colonies along the Konkan coast between Khambhat (Cambay) and Saymur (Chaul, south of Mumbai) were quite large and had considerable autonomy. In the tenth century, al-Masudi wrote that Saymur had a population of about 10,000 *bayasira* (people in India born of Muslim parents) as well as merchants and settlers from Oman, Siraf, Basra, and Baghdad. Their communal leader served at the pleasure of the Rashtrakuta king and was presumably responsible for the appointment of port authorities and other officials who looked after Muslim affairs.

Farther south, Islam was transplanted to the Malabar Coast and Sri Lanka as the lands around the Arabian Peninsula and the Persian Gulf from which Sassanian merchant-settlers originally came converted to Islam. Caste restrictions prevented intermarriage between Muslim merchants and anyone except low-caste Hindu wives,

with whom they often contracted temporary marriages. The offspring of these unions were known as Mapillas, from the Malayalam meaning “big children,” and in time this was the name applied to the community of mestizo Muslims as a whole, which survived until well after the arrival of the Portuguese in the sixteenth century.

Silk Roads Travelers

Travelers along the Silk Roads in the period from 300 to 1000 did not leave behind a rich legacy of written records of their journeys. Because few accounts of their voyages have survived, knowledge about them and their travels is limited. The so-called library of literary, religious, and commercial texts at the Buddhist caves in Dunhuang in today’s western China, an important site along the Silk Roads, attests to the numerous groups represented by the travelers. Works in Chinese, Iranian, Hebrew, and many other languages abound in this remarkable collection, an indication of the diversity of voyagers who passed through this vital stopping place. However, few of these texts yield much information or insight about the travelers themselves. Additional evidence about Silk Roads travelers derives from Tang dynasty (618–907) ceramic figurines, many of which depict images of foreigners. Potters portrayed Arab, Iranian, Turkic, Armenian, and Jewish merchants, horse grooms, musicians, and dancers as well as the horses and camels that transported them along the Silk Roads to China. Although these depictions offer valuable information about their clothing and

➤ FAXIAN—A BUDDHIST TRAVELER ALONG THE SILK ROADS

The travels to India of the Buddhist monk Xuanzang from 629 to 645 have overshadowed the journeys of the monk Faxian (399–414). The Tang dynasty constructed the Great Wild Goose Pagoda in Changan (today Xian) to house the texts and artifacts that Xuanzang obtained during his travels. The emperor treated Xuanzang with great deference, and his fame and popularity led to depictions of him in literature, most prominently in the Ming-era novel *Journey to the West*. Chinese sources did not accord Faxian the same status or renown, and unlike Xuanzang, little is known of Faxian's life and career.

Faxian actually traveled along the Silk Roads two centuries before Xuanzang and charted the course that the more illustrious voyager journeyed. Faxian entered a monastery before the age of ten, but other than that fact, myth and a few unreliable anecdotes shroud his early life. His *A Record of Buddhistic Kingdoms*, an account of his travels, is his principal

legacy. It recounted stories relating to the historical Buddha's life, Ananda's spectacular fiery suicide, and Asoka's virtuous rule. Faxian related these tales in sequence as he visited the sites where these events reputedly took place. Coupled with these Buddhist anecdotes were his impressions of the various kingdoms and regions on his route. He described the environments, customs, and products, enriching China's knowledge of foreign lands.

Unlike Xuanzang, Faxian returned by sea to his native land. He stopped in Sri Lanka for some time and then headed back after a 15-year journey. According to a brief Chinese account, he spent the rest of his life in a monastery, devoting himself to translations of the writings he brought back from his travels. Unlike Xuanzang, Faxian was not accorded a hero's reception and, despite his accomplishments, lived out his remaining years in relative obscurity.

—Morris Rossabi

hairstyles in addition to the musical instruments, weapons, and tools they used and introduced into China, the lack of written sources impedes attempts to provide details about their personalities and adventures.

Travelers encountered numerous hazards along the Silk Roads. Because the roads (or more accurately, trails) were not clearly marked, voyagers could easily lose their way and find themselves in unfamiliar terrain, with the dangers attendant to such uncertainty about the paths to follow. Sandstorms, heat strokes, and hallucinations and mirages caused by overexposure to high temperatures and spillage of water were only a few of the dangers travelers faced in crossing some of the world's most unforgiving deserts. For example, the Buddhist pilgrim Xuanzang journeyed for four days without water after an accidental spillage of the precious liquid. On the other hand, frostbite, icy conditions, avalanches, and altitude sickness posed serious threats to traveling across some of the world's loftiest mountains. As late as the twentieth century, the explorer Aurel Stein had several of his toes amputated due to frostbite. In earlier periods, travelers, who may have taken fewer precautions and

had less access to medical care, most likely suffered more serious and debilitating injuries. Bandits, marauders, and hostile rulers en route were just a few of the human threats.

Merchants were the principal travelers along the Silk Roads and endured the hardships and hazards. They overcame their concerns about such long-distance travels because of anticipated profits from commerce. Elites in Iran, the Arab world, and India were willing to pay exorbitant sums for Chinese silk, while the Tang upper classes traded for horses, exotic animals, aromatics, precious metals, and medicines from West and central Asia. Arab, Iranian, Turkic, and Indian merchants arrived in China, but few Chinese traveled to other lands. Small Islamic and Hindu communities settled in both northwestern and southeastern China, and these foreign merchants often served as middlemen in commerce between China and their respective homelands.

Entertainers and artisans were other groups who traveled along the Silk Roads, mostly to China. Chinese ceramic figurines portray foreign acrobats, musicians, and dancers, many of whom performed at the Tang court. These performers influenced not only Chinese musicians

and dancers but also Chinese clothing and hair-styles. Foreign dress became, for a time, fashionable at the Chinese court, which also valued the works produced by foreign craftsmen. Persian artisans, the era's great silversmiths, created decorative artifacts as well as ritual and ceremonial objects. Central Asian weavers, in particular Uyghur Turks, produced fine textiles, which influenced the motifs and techniques of Chinese textiles. Yet here too no written sources by these craftsmen have surfaced, perhaps because many artisans were not literate.

Buddhist pilgrims did write accounts of their travels. Because literacy was generally required for initiation, Buddhist monks were often literate in one or more languages. Thus, they could and did produce records of their journeys. Most sought to study with the great Indian and central Asian Buddhist masters and to collect Buddhist writings and artifacts. The fifth-century monk Faxian and the seventh-century monk Xuanzang were the most renowned of these Buddhists, perhaps due to their own accounts of their travels. Xuanzang, in particular, returned to China with numerous texts and relics and was greeted as a national hero.

This golden era of the Silk Roads began to end in the middle of the ninth century. The declining Tang dynasty sanctioned a persecution of Buddhism around 845 that spilled over into xenophobia. Even rebels against the dynasty turned against foreigners and blamed them for the Tang's difficulties. Such antiforeignism, coupled

with the dynasty's loss of control of oases and towns in northwestern China and the surrounding regions, undermined the Silk Roads trade. Merchants, envoys, and pilgrims refrained from traveling via the Silk Roads. The Song dynasty (960–1279) did not attempt to recover the oases and towns in northwestern China and central Asia because its officials believed that overexpansion into non-Chinese territories had contributed to the Tang's collapse. Without Chinese control over these lands, trade and travel along the Silk Roads decreased, and the seaborne commerce among India, Iran, the Arab world, and China superseded the land-based caravan trade until the thirteenth-century Mongol invasions.

■ Introduction: Pilgrimages

Going on pilgrimages was a principal motivation for travel in the early medieval age. Pilgrimages were almost always made for religious reasons, and in most religious traditions, one gained particular religious merit by making particular pilgrimages. Many went on pilgrimages to atone for imagined or real transgressions. Some made pilgrimages to shrines hoping to be cured of illness or disease. Women sometimes went on pilgrimages as a curative for failure to bear children.

The business of pilgrimages became a recognized commercial enterprise on pilgrim routes. Guiding pilgrims was an accepted profession, and hostels along the pilgrim routes catered to the pilgrim trade. The temples and shrines, which were the destination of pilgrimages, grew wealthy from the donations made by the pilgrims. Pilgrimages had a cultural impact not only on the pilgrims but also on routes through which the pilgrims passed and, equally important, on the home-

land of the pilgrims. Pilgrimages were culturally broadening.

In Andean civilization, pilgrimages were a prominent feature in most cultures. Especially significant was the venerable pilgrimage site of Pachacamac, which had, since before the beginning of the Common Era, a Pan-Andean reputation comparable to that of the oracle of Delphi in ancient Greece.

In India, too, pilgrimages were a prominent religious and cultural feature. The chief destination for pilgrimages in the early medieval age, as today, was the holy city of Varanasi (Benares), but pious Hindus made pilgrimages to many other sites. In southern India, especially, devout monarchs built temple cities as the foci for pilgrimages.

For Buddhists also, pilgrimage was an important way of gaining religious merit. The Buddhists had developed pilgrimage into an international enterprise. Mahayana Buddhists from central Asia, China, Tibet, and Southeast Asia traveled to Buddhist monastery/university centers in India, of which Nalanda was the most famous. Some of these pilgrims traveled through the mountains and deserts of central Asia to reach India, but many took the sea route, with a stopover at Srivijaya in Sumatra. Indeed, Srivijaya became so important that a major monastery/university at which pilgrims on their way to Nalanda could spend a few months or a few years developed there.

While Jerusalem was still under Roman rule, Christians often traveled as pilgrims there, but after the Muslims seized it, Christian pilgrimages there became less frequent. After that, with the growing centralization of the Western Christian Church, Rome became the favored destination for West European pilgrimage. However, the Golden Era of West European Christian pilgrimage did not commence until nearly 1000 CE, when this period was nearly over.

The most important, from a cultural standpoint and for the sheer number of individuals involved, was the Muslim pilgrimage to Mecca, the hajj. The hajj was and is incumbent on all Muslims who can make the trip. Today, several million people annually make the pilgrimage; in the early medieval age the participants may have numbered several tens of thousands. Its influ-

ence in creating a sense of shared brotherhood among the disparate Muslim communities is difficult to overestimate.

The World of Buddhist Pilgrimages

Buddhism, a missionary religion well adapted to the necessities of commerce and long-distance travel, played an important role in the expansion of Asian trade networks during the first millennium CE. From its location of origin in northern India, Buddhism spread along both land and maritime trading routes to regions of central, East, and Southeast Asia. According to the Buddhist tradition, the Buddha himself enjoined his disciples to make pilgrimages to sacred sites. The *Mahāparinirvāṇa Sūtra* records him telling Ānanda that any devotee who dies while on pilgrimage will be reborn in a realm of great happiness.

For centuries, until Buddhism became firmly established in other countries, India was the essential destination for Buddhist pilgrims from all over Asia. The four most important Indian pilgrimage sites relate to events of the Buddha's life: Lumbini, the place of his birth; Bodhgaya, where he attained enlightenment; Sarnath, the park in which he preached his first sermon; and Kushinagara, where he entered parinirvāṇa (a state of complete enlightenment). This list of four was quickly expanded to eight with the addition of Sravasti, Vaisali, Rajagriha, and Samkasya.

The earliest pilgrimage accounts are those left by Chinese monks, who traveled to India in search of Buddhist teachings and scriptures. The earliest of these is Faxian's *Fo guo ji (Record of Buddhist Countries)*. Faxian began his journey around the year 400 and after walking for five years arrived in the "land of the Dharma," where he stayed for six years collecting Buddhist texts and worshipping at sacred sites. From India, Faxian sailed to Sri Lanka,

➤ XUANZANG

Xuanzang (602–664) is one of the most well-known early Buddhist pilgrims. Departing China in violation of an imperial decree prohibiting foreign travel, he spent 16 years on pilgrimage in India.

Like many seventh-century travelers moving across Asia, Xuanzang followed the Silk Roads, from Liangzhou (present-day Wuwei) to Anxi around the Taklamakan Desert to Samarkand (Uzbekistan) and then down through Taxila (Pakistan) into India. During his journey he visited both Nikāya and Mahāyāna temples and monasteries. In India, Xuanzang studied at the renowned Nalanda Monastery and visited the important locations of the Buddha's life.

While on his journey, Xuanzang made it a point to meet state officials in the regions through which he passed. Upon his return to China he was welcomed at the imperial court. Such was Xuanzang's prestige as a result of having made such an extensive and arduous trip and having returned with Buddhist relics, more than 650 scriptures, and knowledge of the Sanskrit language that Emperor Taizong requested that he write an account of his travels and even urged Xuanzang to participate in the emperor's military offensive against Korea. Due to the political connections that Xuanzang made while on pilgrimage, he played a strategic part in initiating diplomatic relations between northern India and Tang China.

Xuanzang established the Faxiang school of Buddhism and spent the rest of his life translating. His account of his journey is recorded in the *Record of the Western Regions of the Great Tang Dynasty* (*Da tang xi yu ji*), and a fictional account of his life has been popularized in the Ming dynasty narrative *Journey to the West* (*Xi you ji*).

—Alyson Prude

which had become a Buddhist country in the third century and boasted pilgrimage sites of its own, largely in the region of Anuradhapura. Other well-known Chinese pilgrims include the monk Xuanzang, who departed China around 627, and Yiqing, who took a sea route to India via Sumatra. Yiqing traveled with merchant caravans and spent 25 years visiting Buddhist locales, including the famous Indian monastery of

Nalanda, the world's leading center of Buddhist scholarship.

The routes that early Buddhist pilgrims took were the same routes used by merchants, traders, and the first Buddhist missionaries. One of these paths was the Silk Roads. As early as China's Northern Wei dynasty (386–534), there were reportedly 3,000 Buddhist monks living at the Yungning monastery in Luoyang, many of whom were foreigners having arrived with trading caravans via the Silk Roads. Another well-traveled course was the maritime route connecting India and eastern China via the islands of Indonesia. It was via these maritime courses that Buddhism was introduced to Southeast Asia: Myanmar, Thailand, Cambodia, and Laos. Also through the activities of seafaring merchants and Indian immigrants, Mahayana Buddhist practices were introduced to the islands of Java, Sumatra, and Borneo sometime in the fifth century CE. In Java, the temple complex at Borobudur became a popular pilgrimage center, and the kingdom of Srivijaya, established based on its strategic location and control of the Strait of Melaka, enjoyed a brief period of prominence as a hub of Buddhist scholarship and translation activities.

Due to Buddhism's involvement with long-distance commerce, Buddhist pilgrimage sites developed into commercial centers. Similarly, with the establishment of Buddhist temples, commercial centers became pilgrimage destinations. Mahayana Buddhists espoused worshipping Buddha images and relics with material offerings, such as precious stones, fabrics, and incense. The former, in the form of pearls, lapis lazuli, and coral, were important components of luxury trade from India northward to China, and the latter, as silk, was a major commercial item carried from China south toward India. Buddhist pilgrimage thus encouraged and was encouraged by trade and the exchange of luxury goods.

The years up until the seventh century mark a period of Buddhism's importation to and domestication within Asian countries outside India. Emperors and local rulers, attempting to use Buddhism to legitimize their rule, encouraged the adoption of Buddhist practices, financed the construction of temples and monasteries, and sponsored monastic pilgrimages to acquire

scriptures and relics. Empress Wu of China (r. 690–705), for example, employed Indian monks in her court both to translate Buddhist scriptures and to validate her claim to sovereignty over the Buddhist continent. The role of Buddhist rulers in importing relics and establishing local sacred sites played a key role in Buddhism's establishment in lands beyond India.

While written texts remained the provenance of monks and the educated elite, relic veneration and pilgrimage were practices in which the common people, largely illiterate and from the middle and lower classes, could participate. Devotees flocked to worship relics brought by pilgrims and itinerant monks, and local pilgrimage destinations developed at places of reported miracles and at former dwellings of native Buddhist saints. In East Asia, the first of these was China's Wutai Mountain, recognized in the seventh century as the abode of the bodhisattva Mañjur. Its designation as the home of Mañjur is ascribed to the many visions of the bodhisattva seen by early visitors to the site. The Korean monk Jajang reported encountering Mañjur there in 636, at which time the bodhisattva allegedly instructed him to establish a similar pilgrimage tradition in Korea.

With the grounding of Buddhist study and practice in China and the recognition of sacred sites on Chinese soil, China became a pilgrimage destination of its own. Most pilgrims to China came from Korea and Japan, but even Buddhist devotees from South Asia and India made the journey to worship in China. Japanese Buddhist monks who requested government sanction to accompany official emissaries to China include Koba Daishi (Kokai in Chinese), popularly believed to be the founder of the 88-site Shikoku Pilgrimage in southern Japan. Another important pilgrimage circuit in Japan included the 33-site Kwannon Pilgrimage, revealed in a vision to the eighth-century abbot Tokudo Shinin.

Hajj, or Pilgrimage, to Mecca

The annual pilgrimage to Mecca was one of the most important elements of Islam in fostering a far-flung community of believers and in promoting a unified Islamic culture. Yearly, Muslims from places as diverse as Spain, central Asia, northwestern India, Iran, the Sahara, and the Indian Ocean littoral made the journey to participate in the most hallowed rituals of the Muslim faith. People of several cultures, ethnic groups, and social classes made the hajj, during which these differences were ignored and believers interacted on a basis of equality.

The Muslim religion has five pillars, that is, central requirements that all believers must observe. One of these is the obligation to undertake a hajj, or pilgrimage, to the Holy City of Mecca at least once in a lifetime. However, those who are ill or cannot afford it are excused. On the other hand, to make it possible for someone else to do a pilgrimage is meritorious, and those who die while on pilgrimage are blessed. The actual pilgrimage lasts for five days during the month of Dhul al-Hijja, though many pilgrims take longer than this. Everyone must do a fixed set of rituals and practices with all the other participants in Mecca and surrounding areas. These include moving around the Kaaba, or sacred stone set in the middle of the Great Mosque in Mecca; moving to the plain of Arafat, stoning rocks representing devils at Mina; and then returning to Mecca to circumambulate the Kaaba again. Pilgrims have to wear very simple clothes, called the ihram, and sexual relations and bad conduct are banned during the hajj period.

The rites and ceremonies of the hajj follow the practice of the Prophet Muhammad when he made his Pilgrimage of Farewell in 632 CE shortly before his death. On this occasion 200,000 followers assembled to hear his vision

► THE EARLIEST ACCOUNT OF A PILGRIMAGE— NASER-E KHOSRAW OF PERSIA, 1050 CE

This is an account of the umrah (minor pilgrimage), which however is the same as the start of the longer rituals of the complete hajj:

“For people who have come from faraway places to perform the Minor Pilgrimage, there are mile-stones and mosques set up half a parasang [about 3.5 miles] away from Mecca, where they bind their ihram. To bind the ihram means to take off all sewn garments and to wrap a seamless garment about the waist and another about the body. Then, in a loud voice, you say ‘Labayk Allahumma, labayk’ [I have answered thy call, O God], and approach Mecca. . . . Having come into the city, you enter the Haram [Great] Mosque, approach the Ka’ba, and circumambulate . . . always keeping the Ka’ba to your left shoulder [in other words, counterclockwise]. Then you go to the corner containing the Black Stone, kiss it, and pass on. . . . Afterwards you go to the Well of Zamzam, drink some water or rub some on the face, and leave the Haram Mosque. [After running seven times between Safa and Marwa] you find a bazaar with about twenty barber-shops facing each other. You have your head shaved and, with the Minor Pilgrimage completed, come out of the Sanctuary.”

of an all-encompassing political, social, economic, and spiritual Islam. Delivering his sermon on Mount Arafat, Muhammad espoused a belief in one God, the equality of all Muslim believers, the sanctity of life, property and honor, women’s rights, and the notion of the Ummah, or Muslim, community.

The Holy Book, the Quran, recommends the hajj: “And proclaim that the people shall observe Hajj pilgrimage. They will come to you walking or riding on various exhausted [means of transportation]. They will come from the farthest locations.” Elsewhere it lays down that the “Hajj shall be observed in the specified months. Who-

ever sets out to observe Hajj shall refrain from sexual intercourse, misconduct, and arguments throughout Hajj. Whatever good you do, God is fully aware thereof. As you prepare your provisions for the journey, the best provision is righteousness. You shall observe Me, O you who possess intelligence.”

As the Muslim religion spread rapidly in the first century of its existence—that is, to around 730 CE—we can assume that increasing numbers made the journey to Mecca. However, we have no estimates of how many made the hajj in this period. The first travelog recording a hajj dates only from 1050. Figures from slightly later give us some indications. In 1279, 40,000 came from Egypt, and the same number from Iraq and Syria. In 1324 it was estimated that 15,000 believers from Africa south of the Sahara Desert came on hajj. It must be remembered, however, that the Muslim world at this time was much more constricted than was the case later. Even as late as 1000 CE, Islam had not spread far beyond the Arab world, Persia, North Africa, Iberia, and the area of Pakistan. Conversions in sub-Saharan Africa, India, and Southeast Asia were yet to come.

The pilgrimage to Mecca was obviously primarily a religious event. Those who had undertaken the long and dangerous journey to the Holy City were much esteemed on their return home and were entitled to give themselves the title of hajji, one who has done the hajj. Such people were treated with great respect. Those people who stayed in Mecca for some time, doing several hajjs and studying in the religious schools in the town, were even more influential. When they went home they taught others how Islam was practiced in Mecca itself. This served to standardize the faith. People all over the Muslim world tried to follow the rituals and practices of the authorities in Mecca.

Santiago de Compostela and Other Christian Pilgrimages

By legalizing Christianity, Emperor Constantine opened the roads of the Roman empire to Christian pilgrims. His mother's identification of the places associated with Jesus's life in and around Jerusalem and his construction of large religious shrines in Jerusalem, Rome, and Constantinople facilitated the visitation of devout believers. Out of devotion to Christ and the saints or as a penance for sin, Christians journeyed from near and far to place themselves in the presence of the holy, to pray, witness miracles, and perhaps obtain a holy relic to take back home. Before leaving home, pilgrims received blessings from their family, friends, and clergy and made their last wills.

Jerusalem had long drawn pilgrims and remained the ideal destination. As the cult of saints developed, however, the pious were drawn to local and regional shrines where martyrs were buried or relics were displayed. Rome could brag Saints Peter and Paul, Alexandria (and later Venice) hosted Saint Mark, Compostela in Spain claimed Saint James, and Constantinople became a veritable warehouse of holy relics, especially those of the Apostles. Later saints developed their own cults that drew the faithful: Saint Symeon Stylites at Qal'at Seman in Syria, Saint Demetrios in Thessalonike, Saint Martin at Tours, Saint Martial at Limoges, Saint Brigid in Kildare, and Saint Alban in England. People often traveled hundreds of miles, usually on foot, to make their pilgrimage, and journeys could be long and hazardous. They shared the roads—often old Roman highways to major sites—with merchants, traveling clerics, and vagabonds. Pilgrims could fall prey to inclement weather, illness, accidents, and thieves. The wealthy could be arrogant and violent, and the poor could be demanding of their hosts along the way. Women travelers often met resistance from male-controlled shrines and houses of hospitality, and commentators warned of the dangers to women's virtue and very lives. Along major routes religious orders and their charitable patrons provided hospices, baths, chapels, and other accommodations. Pilgrims gained certain privileges such as free hospitality and ex-

▶ FEMALE PILGRIM FROM SPAIN IN JERUSALEM, CIRCA 400 CE

"On arriving at Gethsemani a suitable prayer is first said, followed by a hymn, and then a passage from the Gospel describing the arrest of the Lord is read. During the reading of this passage there is such moaning and groaning with weeping from all the people that their moaning can be heard practically as far as the city [Jerusalem]. And from that hour everyone goes back on foot to the city singing hymns, and they arrive at the gate at the hour when men can begin to recognize one another. From there, throughout the center of the city, all without exception are ready at hand, the old and the young, the rich and the poor, everyone; and on this day [Friday] especially no one withdraws from the vigil before early morning. It is in this fashion that the bishop is led from Gethsemani to the gate, and from there through the whole city to the Cross.

When they finally arrive before the Cross, it is already beginning to be broad daylight. There then is read the passage from the Gospel where the Lord is led before Pilate, and whatsoever words are written that Pilate spoke to the Lord or to the Jews, all this is read. Afterwards, the bishop addresses the people, comforting them, since they have labored the whole night."

Egeria: Diary of a Pilgrimage, translated by George E. Gingras, 109–110 (New York: Newman, 1970).

emption from tolls, which led unscrupulous travelers to pretend to be pilgrims themselves. Towns along popular routes developed service industries to meet the pilgrims' needs for food, shelter, and health care, and churches developed their own collections of relics to draw the traveling faithful and their offerings.

Political and social changes could affect trends in pilgrimage. Islamic conquest of much of Byzantium ended Christian control of many sites; the conversion and rise of the Franks and conversion of the Anglo-Saxons and continental Saxons by Roman missionaries stimulated pilgrimages to Rome; Saracen threats in the Alpine

passes may have shifted tenth-century north-west European pilgrim traffic away from Rome to French shrines and Compostela; and the destruction of the Holy Sepulcher shrine in Jerusalem by Caliph Al-Hakim in 1009 reinvigorated the Latin West's interest in Jerusalem.

Christian Pilgrimage to 1000 CE

Christian pilgrims made long and often dangerous journeys to place themselves in the physical presence of the holy. Their destinations included places where Jesus lived and taught, especially Jerusalem, where he suffered and died, and

places that contained the remains, or relics, of both holy men and women. The collection of bodily remains and objects used by these saints began early in the Christian era, amounting to a “cult of the saints” by late antiquity. Church fathers and clergy preached that divine favor was associated with the saints and that veneration of their relics pleased the saints who had God's ear. Just as Christians were drawn to the presence of living holy men and women, such as great preachers or wise hermits, so too were they drawn to the places sanctified by Jesus or to the relics of his saints.

Shrines of local martyrs drew the earliest pilgrims, but as Christianity was legalized and crystallized throughout the Roman empire, the devout sought other places of note. In the city of Rome, Emperor Constantine erected churches over the graves of the apostles Peter and Paul, and Pope Damasus turned the Colosseum and Christian underground cemeteries, or catacombs, into martyrs' shrines. Constantine's mother, Helena, traveled as a pilgrim to the Holy Land and had church-shrines built on sites associated with Jesus's life and passion, returning with precious relics for display and veneration. Reports of miracles, especially healings, associated with shrines circulated widely. Pilgrims were convinced that any object they brought into contact with saints' tombs, relics, or reliquaries that housed them became sacred and might have miraculous powers. Oil that was used in shrine lamps, water that was poured over a shrine, and even dust or dirt was collected, handed out, or sold at sites. Pilgrimage evolved into a penitential act, with pilgrims humbling themselves as they sought forgiveness from the divine Judge. Rituals and special liturgies developed at major shrines for the sake of pilgrims. Eventually monastic and cathedral churches began to collect relics, themselves becoming destinations for the pious, both local and foreign.

The most famous destination developed in the ninth century at Compostela in northwestern Spain around the purported grave of the Apostle James, or Santiago. Mid-tenth-century documents record visits by nobles, high clergymen, a Viking, and even an Armenian hermit, all

► GREGORY OF TOURS ON VISITING ST. PETER'S SHRINE

Gregory of Tours wrote of his visit to St. Peter's Shrine in Rome during the sixth century:

“He who wishes to pray before the tomb opens the barrier that surrounds it and puts his head through a small opening in the shrine. There he prays for all his needs and, so long as his requests are just, his prayers will be granted. Should he wish to bring back a relic from the tomb, he carefully weighs a piece of cloth which he then hangs inside the tomb. Then he prays ardently and, if his faith is sufficient, the cloth, once removed from the tomb, will be found to be so full of grace that it will be much heavier than before. Thus will he know that his prayers have been granted.”

of whom sought the saint's favor. After 1000 the land routes across southern France and northern Spain to Compostela developed into the most famous pilgrimage road of the Christian Middle Ages, dotted with monasteries, chapels, and hospices for the thousands who made the arduous journey each year.

Politics and Statecraft

Theme 4: Politics and Statecraft: Introduction discusses governments, states, and empires in the Era of Expanding Regional Civilizations.

By the fourth century CE, the great majority of the earth's people were sedentary village agriculturalists, while a very small minority were nomadic hunters and gatherers. Although they occupied huge stretches of territory, such as Australia, most of Siberia, the deserts of southern Africa, and much of North and South America, few if any of the hunting and gathering bands had any sign of formal governing apparatus.

In large sparsely populated areas where there were no cities, most of the sedentary agriculturalists had only rudimentary governing institutions. They lived in nearly autonomous villages without the governing apparatus of states. Sometimes these villages were egalitarian, but often a chief dominated them politically. These chieftaincies were frequently hereditary, as was the case with the Celts, Germans, and Slavs beyond the frontiers of the Roman empire; most of the inhabitants of the African forests and the East African savanna; the Polynesians and other inhabitants of Oceania; and many of the indigenous agricultural peoples of the Americas.

These chieftainships became states when populations increased and their governance became so complex that professional administrators (bureaucrats) were required. States are defined as political entities that have formalized administrative systems for taxation or tribute gathering, the redistribution of state revenue, etc.: in other words, political systems with bureaucracies. Empires are large states that are themselves agglomerations of smaller states. They are often multicultural and multilingual political entities, created by military force.

States and empires needed armies for their defense or conquest, but soldiers could seldom organize and govern states without bureaucrats to collect taxes, administer the laws and decrees of the governing power, and organize and execute public works such as irrigation systems, defensive walls, and roads as well as palaces and monuments (to advertise the greatness of the governing power). In addition to an army and a bureaucracy, all successful states, to legitimate themselves and to envelop their ruler with an aura of the sacred, subscribed to an ideology, an organized religion. During this period all states were identified with a religion; there

In addition to an army and a bureaucracy, all successful states, to legitimate themselves and to envelop their ruler with an aura of the sacred, subscribed to an ideology, an organized religion.

were no secular states, not even China, as has been claimed by some historians.

Nomadic pastoralists, who inhabited the vast grasslands of the Eurasian steppe as well as the savannas south of the Sahara and the Arabian and Sahara deserts, usually traveled in small groups, governed by kinship bonds. Although they sometimes did coalesce into powerful tribal confederations, these usually proved to be ephemeral. Occasionally, however, they conquered the farming folk and became sedentary themselves.

The years from 300 to 1000 mark a fecund period for the formation of new states and empires. New states and empires grew by appropriating and refashioning the governing systems, the rules, customs, ideologies, and especially the bureaucracies of the fallen states that they replaced, or by absorbing, by diffusion, these elements from a successful neighboring state. It was not necessary to reinvent the basic elements needed for state creation. These elements emerged anew only a few times in human history: in the ancient Middle East, India, China, Mesoamerica, the Andes, and the West African Sudan.

In the year 300, the Roman and Sassanian empires dominated and contended for the western part of the Afro-Eurasian ecumene, the Guptas were creating an empire in India mimicking the model of the Mauryas and Kushans, and in China several ephemeral dynasties and kingdoms contended to fill the vacuum left by the downfall of the once mighty Han dynasty. In both Mesoamerica and the Andes, the elements of state building had been developed, and the first empires, Wari and Tiwanaku, were emerging. In Africa south of the Sahara, Axum and the Nubian kingdoms, inspired by examples from the Mediterranean region, were growing. In West Africa, city-states and kingdoms were also rising; whether as a result of outside example or because of internal dynamic is a question not yet resolved.

During the seven centuries of this period, many new states would rise, but all owed their creation to the examples of preceding or existing states. Successor states emerged when groups conquered parts or all of existing states, appropriating their governing systems and some of their bureaucratic personnel in the process, as was the case with the Germanic kingdoms, the Gupta empire, or the empire of Ghana. Other states, such as Japan, Kievan Rus, and Funan (Cambodia), emerged in areas where previously there had not been states, but they were able to build the elements of state governance by learning from the example of neighboring states. Usually these elements of governance were part of a transfer of culture that included a religion, such as Buddhism, Christianity, Islam, or an amalgam of Hinduism/Buddhism.

The Tang dynasty, one of the two early medieval superpowers, rose in a civilization where the elements of governance were well developed and deep rooted. Tang succeeded by overthrowing the Sui, which had united China after a three-and-a-half-century period of division, but the elements of governance that had developed during the Han and preceding dynasties survived in each of the fragments into which China had been divided. It was only necessary for the Sui and Tang to reassemble these elements, including the scholar bureaucracy and the Confucian

system. In addition, the Tang used their patronage of Buddhism to increase the legitimacy of their state.

The Muslim caliphate, the other early medieval superpower, was created by conquerors from the Arabian Desert, but it succeeded only by appropriating the governing systems of the vanquished Sassanian empire and the richest provinces of the Roman empire. In its first century, the caliphate used Persian and Byzantine administrators as well as the Persian and Greek languages for its government.

Most early medieval states and empires had similar anatomies. The heart and brain of these political organizations were the capital. There were located the ruler's family and household, the high bureaucracy, and the capital army together with the armaments makers, the poets who sang of the ruler's glory, the high clerics and monasteries that gave the state its spiritual legitimacy, and the thousands of servants and other people necessary for the care and feeding of all these important functionaries. Some early medieval capitals were very large. It is estimated that the Tang capital, Chang'an, housed up to 1 million people in the walls and perhaps as many outside, while Baghdad may have had in excess of 800,000 and Teotihuacan, the Mesoamerican metropolis, perhaps 300,000. East Asian capitals were planned on a gargantuan scale. The capital of Silla was said to have housed several hundreds of thousands, but Heian in Japan, modeled after Chang'an, never reached the enormous size originally planned for it.

The well-being of the capital came to be the chief concern of most states. The Tang dynasty constructed an elaborate canal system to transport food to Chang'an. The Persian Sassanian empire built its capital, Ctesiphon, not in the Persian heartland but rather in bountiful Mesopotamia, where it could be more readily supplied.

Besides the revenue-consuming capital, medieval states had a revenue-producing hinterland. Successful states were careful to maintain the health of the hinterland provinces by, minimally, maintaining irrigation systems and administering laws in a way that promoted stability. In addition, governments usually sought to secure the loyalty of the hinterland by supporting religious establishments and building monuments designed to reflect the ruler's magnificence.

Medieval states were also very concerned with their frontiers. The defense of frontier competed with the maintenance of the capital as a consumer of revenue, and because large armies were normally stationed on the frontier, it was always a source of danger for the central government. Ambitious frontier generals launched many great rebellions. Some of these rebellions, such as that of An Lushan in mid-eighth-century China, came close to toppling the regime. The rebellion of Arab armies in central Asia did overthrow the Umayyad caliphate and established the Abbasid caliphate in the mid-eighth century.

Empires varied in geographical configuration. Tiwanaku in the Andes, for example, resembled more an archipelago than a compact empire. The heartland of Tiwanaku was in the fertile area near the shore of Lake Titicaca, but the Tiwanakan metropolis sent out colonists to develop resources in a variety of ecological zones. These colonies were like islands in territory over which Tiwanaku did not exercise control.

All early medieval states and empires had a variety of groups who performed various functions. Most important were the revenue-producing classes, particularly the peasantry. The status of the peasantry ranged from free landowners to various degrees of unfreedom, including serfdom and even slavery. Some states, such as the Byzantine empire (ca. 750–1000) and the Tang dynasty in its early phase, drew copious revenue and numerous army recruits from their free peasantry and passed laws to protect their freedom. At other times and in other

States developed bureaucracies to collect taxes as well as to control and regulate the revenue-producing classes. These bureaucrats were professionals, such as those trained as Confucian scholar bureaucrats, as in China, or as members of the Christian clergy, as in western Europe or Ethiopia.

states, the peasantry was cruelly exploited, living on the edge of starvation in good years and visited by famine in years of scarcity. The Byzantine empire and the Tang dynasty both tried to maintain an independent landowning peasantry.

States developed bureaucracies to collect taxes as well as to control and regulate the revenue-producing classes. These bureaucrats were professionals, such as those trained as Confucian scholar bureaucrats, as in China, or as members of

the Christian clergy, as in western Europe or Ethiopia. As already stated, the Caliphate used Byzantine or Sassanian bureaucrats in its first century but after that relied increasingly on administrators educated in religious schools and trained on the job. In western Europe, where the elements of statehood developed in Roman times had atrophied to some degree, the bureaucracy was likewise weakened. Local landholders, churchmen, and warriors undertook many of the functions previously performed by government administrators.

The armies were another important group. In the larger empires, there were two kinds of armies: the capital army and the frontier armies. The frontier armies defended the empire against foreign invasion; the capital army defended the capital against rebellious frontier armies. In the times of their greatest military power, both the Byzantine empire and the Tang dynasty manned their armies with levies from the peasantry, but after the decay of peasant freedom, both empires increasingly recruited mercenary professional soldiers for their forces. In the Muslim caliphate during its Umayyad period, the soldiers were usually Arabs or converted Muslims who often served for religious reasons. Under the Abbasids, however, Arabs were increasingly banished from the armed forces, their places being supplied by mamluks, or slave soldiers, usually Turkish but often Slavic or African. From time to time the bureaucrats called in the army to suppress peasant uprisings. Nearly as often the armies intervened in politics, deposing rulers and elevating others.

The great landholders and the nobility were powerful interests in most early medieval states and empires, holding varying degrees of political power. Usually, they controlled political power at the local level, and often their lands and peasants were immune from taxation. Very seldom could a state impose its dictate on local areas without first negotiating with the local magnates, who often fielded their own armed groups and local militias. In medieval western Europe and in the Sassa-

nian and Gupta empires, the local landholders and soldiers were formally invested with political power over their areas, and the army of the ruler consisted largely of feudal levies led by the local aristocrats who, in western Europe, were often also powerful clerics.

The chief functions of early medieval states were always stated in religious terms, but the sociologic and economic functions were to maintain the status of the ruling group and to transfer wealth from the peasants, craftsmen, and merchants to the ruling group. Indeed, many states, such as the Germanic kingdoms, Kievan Rus, and the Muslim caliphate, started frankly as kleptocracies (thievery states) but soon, realizing that the revenue potential of their conquests depended on the prosperity of the conquest, assumed other functions. Defending against foreign invasion, keeping law and order, maintaining irrigation systems, protecting trade routes and markets, and supporting and promoting the official religion were all functions of the early medieval state.

All early medieval states embraced and supported an official religion; some, such as the Tang dynasty, supported a number of religions. These religions, whether Buddhism in East Asian lands, Hinduism in South and Southeast Asia, Islam in the caliphate, or Christianity in Europe, Ethiopia, and Byzantium, legitimated the state and enveloped the ruler in a sacred aura. In the early medieval age, there was no separation of church and state; each symbiotically supported the other.

All early medieval states had roughly similar life cycles. All states were strong and flourishing in times of prosperity. When the agricultural classes were healthy, when the bureaucracy functioned well, and when citizen soldiers under a vigorous government manned the armies, early medieval states thrived. But when rulers were weak, when civil war or wars of succession wracked the state, when mercenary armies became exorbitant in their demands, or when floods, droughts, and other disasters combined with official corruption to further injure the suffering peasantry, then rebellions, often led by religious sectarians, such as “heretical” Christians, Shias, or Daoists, erupted, leading to regime change.

The life spans of some empires in the Era of Expanding Regional Civilizations were short. Many lasted only a few generations. Others lived to an old age of almost 300 years, but few exceeded that. The Byzantine empire was a miracle of longevity, enduring until 1204 and then after its reestablishment in 1261 until 1453.

■ Introduction: Sources of Political Power in the Early Medieval Age

In the period 300–1000 CE, many new states were established. Most of these new states grew out of chieftaincies, especially those that emerged in Inner Eurasia, West Africa, and

Mesoamerica. These chieftaincies became states by developing an institutionalized structure, with a professional bureaucracy and an institutionalized military force. These new states usually

imported their bureaucratic expertise from existing states. Missionaries from universal religions such as Christianity and Buddhism supplied this political capital by serving in the administration of the new states. Some new states that emerged on the ruins of collapsed empires, but some emerged from the fragments of established states and usually harvested the available political capital left by the defeated empire by employing the bureaucrats of the old empire. This was especially evident in the early Islamic caliphate, where the bureaucrats and the political apparatus of the defeated Sassanians and Byzantines were the foundation of the new Islamic empire's administration. In Tang China, which was the wealthiest and most populous and politically sophisticated state of the age, great efforts were expended in recruiting and training government officials. In the Tang system, officials were recruited through an elaborate examination system in which candidates were tested not only for their competence but also for their adherence to official cultural norms.

All successful early medieval states developed a governing rationale, or philosophy of governance. Usually this governing rationale was couched in religious terms and was part of the official religion of the state. The thrust of the governing rationale was that the state was divinely instituted, that the ruler of the state was enveloped in a sacred aura, and that loyalty and obedience to the state were religious duties for all inhabitants of the state.

This was true in China (where the emperor was believed to have been given a mandate from heaven) as well as in Muslim, Christian, Buddhist and other lands. Often, the founders of states consciously searched for a universal religion to provide this kind of legitimacy. Such was the case with the ruler of the Uighur empire, who decreed Manichaeism to be the state religion; the khagan of the Khazar, who urged his subjects to adopt Judaism; or the Slavic states of central and eastern Europe, which were proselytized by both Orthodox and Catholic missionaries. A similar process occurred in East and Southeast Asia, where the new states in Korea, Japan, and Southeast Asia sought to legitimize them by adopting Buddhism or, less frequently, Hinduism as their court religion.

In Mesoamerica a similar process was evident. The rulers of the Maya city-states also claimed a unique relationship with the gods. In the early medieval age, almost all states were kingdoms, ruled by hereditary monarchs.

Kingdoms, started by armies, institutionalized by bureaucracies, and legitimated by religions, could be fragmented by religious schisms or succession crises. Religious fissures were usually avoided by the enforcement of official orthodoxy and the punishment of heresy. Rules of succession, usually by the first son, were important for the unity of the kingdom, but often there was no accepted system of succession to the throne. This resulted in frequent wars of succession, as in Merovingian and Carolingian Francia.

To sum up, the principal supports for political power in early medieval states were

- 1) An army to seize or impose power. An army, it has been said, could conquer a kingdom but could not govern a kingdom.
- 2) A trained and professional bureaucracy to collect taxes, administer law, construct public works, etc. The bureaucracy was the key to governing.
- 3) An official religion to get support or acquiescence from the people and win legitimacy for the kingdom.
- 4) A system of orderly succession to power to ensure unity and prevent wars of succession.

Muslim Political Thought, 632–1000 CE

At its height in the eighth century, the caliphate (from *khalafa*, “to succeed,” and *khalifa*, “deputy”) ruled over territories extending from North Africa to the Indus River, but its impact on the early medieval world was even larger. One only needs to consider the flow of goods and ideas between the East and the West and the resulting exchange among cultures to understand the impact of the caliphate on the early medieval world. Studying the political thought and practice in this large, prosperous, and dynamic entity requires a truly world-historical

context, as the caliphate integrated to its evolution the existing heritages and traditions of the late antique world.

The caliphate emerged after the death of Prophet Muhammad (570–632). The first four caliphs, all elected to the office, organized very successful conquests in Iran, Byzantine Syria, and Egypt and built the initial administrative and fiscal institutions of government. Success brought controversy and conflict. The first major rupture in the history of the caliphate was the first civil war (656–661), which led to the collapse of the Rashidun (the rightly guided caliphs) and the ascendancy of the Umayyads (661–750). The ostensible cause of the conflict was the assassination of the third caliph, Uthman, and the hesitation of the fourth caliph, Ali, to pursue the killers. However, a much more complex dynamic lay behind this simple *casus belli*. The early Muslim conquests, which in merely three decades slashed the Byzantine empire in half and exterminated the Sassanian empire, and its corollary socioeconomic transformation caused tension within the society on many levels. The civil war involved a manifold confrontation among the cultural, sociopolitical, and economic centers and the discontent periphery in a polity too rapidly expanding and changing.

The governor of Damascus, Uthman's clansman Mu'awiya, rose against Ali, demanding that the murderers of Uthman be brought to justice. The disagreement turned into military conflict, at the indecisive end of which Ali and Mu'awiya agreed to negotiate. However, the negotiation came to a stalemate, leading to the disillusionment of some of Ali's supporters. They questioned his sincerity and legitimacy. They maintained that he should not have negotiated with Mu'awiya had he thought he was right. They split from his ranks and thus were named the Kharijites, and they became a mortal enemy of both Ali and Mu'awiya. Ali was shortly assassinated by one of the Kharijites (the assassin targeting Mu'awiya was captured and killed), leaving Mu'awiya the *de facto* ruler; he was immediately announced caliph. The supporters of Ali rallied around his sons shortly after his death and formed the seed of the Shia political action during the Umayyad caliphate. Umayyads continued the conquests and reorganized the adminis-

Uthman was the third successor to Muhammad as head of the early Islamic community. The chief problem with which Muslim political thinkers wrestled concerned the legitimacy of the caliph, or ruler. Uthman's caliphate is viewed as illegitimate by Shia and other Muslim minorities. (Victoria & Albert Museum, London/Art Resource, NY)

tration to assert central authority and pacify the provinces.

Under the Umayyads the election gave way to succession. But as the second civil war in 684 shows, the succession dispute was problematic even within the Umayyad family. The Umayyad caliphs organized their administration, and the power of the caliphs increased. And so did the force of the opposition to them. It appears that the rhetoric of the political debate during the Umayyad dynasty focused on the key concepts of election versus succession (*shura* vs. *wiratha*). The Umayyads defended their right to appoint their successors from among their family members. The nonsectarian conglomerate of proto-Sunnis—for example, the broad community of faithful, the Kharijites, and the Qadarites, the supporters of freewill—demanded the return to election. Various Shia trends advocated the appointment of the one agreed upon from the family of the Prophet.

The third civil war brought the Abbasids to power (750–1258). The Abbasids, in reference to

THE NECESSITY OF IMAMS

“They have disagreed on the necessity of imamate and on searching for an imam and appointing him. The majority of our colleagues [Sunnis] from among the theologians, the jurists, together with the Shia and the Kharijis and the majority of the Mu’tazilis, has acknowledged the necessity of imamate and [agreed] that it was a religious obligation requiring obedience to whoever was appointed for it. [They also agreed] that the Muslims need an imam to execute their laws, implement verdicts, lead their armies, conduct the marriage transactions of slave girls, and distribute revenues among [the members of the community]. A small faction from the Qadariyya, such as Abu Bakr al-Asamm and Hisham al-Fuwati, disagreed with our colleagues. Al-Asamm claimed that if people refrained from harming each other, they could do without an imam. [On the other hand], Hisham claimed that if the community brought its word on the truth together, then it would need [to elect] an imam. However, if it rebelled, sinned, and killed the imam, it would not be necessary for the

people of the truth to institute an imam. [Baghdadi goes on:] The companions of the Prophet Muhammad have agreed in consensus on the necessity of the imamate. There is no value to Al-Asamm’s and al-Fuwati’s objections in this matter because of a preceding consensus to the contrary of their views. Religious law (*shari’a*) has brought injunctions that can be handled only by an imam or his appointee, such as the execution of verdicts on the free [members of the community]—notwithstanding the disagreement on the authority of slave owners to apply lawful punishments on their slaves—, and marrying girls who have no custodians according to the view of the majority of the community, and holding the Friday prayers and Muslim Festivals, according to the people of Iraq” (translation by author).

the uncle of the Prophet Muhammad, Abbas, led a revolt against the Umayyads advocating the right of the family of the Prophet to rule. Once caliphs, however, they did not practice election. They excluded even the Alids from the caliphate and implemented a stricter line of succession. They alienated not only the Kharijites, who would almost disappear from the political scene after the middle of the ninth century, but also the Shia, who were their supporters during the third civil war. Even the more sympathetic proto-Sunnis and Mutazilites preferred to maintain mostly cordial but not overly supporting relations with Abbasid caliphs. The Mutazilite was a theological sect favoring rational reasoning and argumentation in religious thought. It emerged in the early eighth century and waned by the twelfth century but has nevertheless continued to exercise great influence on Islamic theology.

In retrospective, all caliphs until the demise of the caliphate in the middle of the thirteenth century were from the tribe Quraysh. The ascension to office was either by some sort of election, appointment by the ruling caliph, or

simply through military force. The caliph was appointed for life, and there was no particular constitutional law outlining his responsibilities and privileges clearly. This does not mean, of course, that he was a tyrant free to exercise whatever he wanted. He had to negotiate his authority with prevailing social classes, religious scholars, sectarian formations, military and administrative classes, and the political culture of his milieu. Certain qualifications (intelligence, good moral conduct, military prowess, physical ability to attend his duties, male, Qurashite in descent) were sought in the candidate, but there was no institutional oversight. Most of the time political necessities dictated the appointment of a particular individual to the office. It seems that political thought was greatly influenced by this historical practice whether in the form of adoption or counterargumentation.

As a result, the initial ideas on politics involved mainly subjects closely relevant to political legitimacy and the qualification of the ideal candidate. Among such matters were the problem of freewill and predestination (*qadar* and

jabr), the definition of faith (*iman*), the identification of the most meritorious of the earliest caliphs (*afdaliyya*), and the debate over election versus succession. Ironically, as the political power of the caliphate was diminishing in the middle of the ninth century, theoretical expositions of the caliphate began to emerge. Major intellectual traditions seem to have delineated the broad outlines of their political views by the eleventh century, among which one may isolate several distinct paradigms: Sunni legal paradigm, Shia discourse of imamate, Mutazilite rationalism, *siyasa* (or practical governance) expounded by Abbasid secretaries and belles lettres, and political philosophy.

The rise of the ulema (literally, the learned; technically, religious scholars responsible for elucidating religious law and theology) since the early eighth century was one of the most significant developments in medieval Islamic history. The ulema came to mediate between the caliphs and their subjects and represent the rights of the community against the power of the caliphs. In this role the ulema carried a great social and political weight. However, the ulema could not oppose the caliphate as illegitimate, for the legitimacy of all transactions, secular and religious, was tied to the caliphate. The ulema therefore stood in support of the historical caliphate even though they were careful to emphasize their independence from it and stress the distinction between the real caliphate (the period of the first four caliphs and/or the ideal theoretical caliphate) and kingship. They came to agree that the caliphate was based on religious law (Sharia) and by and large took for granted that political society was a religious necessity. They maintained that the caliph was in charge of enforcing mundane laws and the observance of religious ordinances. This was a principle intended to subordinate the caliphate to religious law.

According to the Sunnis, the caliph should be elected to office rather than being secretly appointed or divinely ordained. In this the Sunnis agreed with the Kharijites and the Mutazilites but fell apart from the Shia, who maintained that the incoming imam was appointed by the current, divinely sanctioned, and infallible one. The majority of the Mutazilites and the Kharijites saw the imamate as a rational necessity. But

many Mutazilites and Kharijites thought that the imamate was neither necessary nor religiously obligatory. For the Shia, it was a grace of God since he would not leave his creatures without guidance. Sunni political views were expounded in jurisprudential work, *hadith* (traditions attributed to the prophet Muhammad) collections, and the works of theology beginning with al-Ashari (945) in the tenth century. The most elaborate and far-reaching discussion of the caliphate from the Sunni-Juristic perspective was made by the jurist al-Mawardi (1058).

The *siyasa* genre (literature on practical ethics, mirror for princes, practical and moral advice to rulers) was initially associated with government secretaries since the middle of the eighth century but encompassed later diverse literature from various walks of life. The advice literature, deriving largely from the Sassanian imperial tradition and culture but also inspired by Greek tradition, aimed at advising rulers to improve their government and promote a courtly etiquette for appropriate royal conduct. The impact of this genre and its advocates on the practice of the caliphate cannot be overestimated. It was thanks to this genre that the caliphs were increasingly modeled on the Sassanian emperors, projecting a grandiose image aloof from their subjects, an almost divine or semidivine ruler. The egalitarian notion of *umma* (Muslim community) among the Sunni, Kharijite, and Mutazilite theorists was incompatible with the hierarchical social order and therefore drew the antagonism of the ulema to secretaries and their political views. This was a clash between religious egalitarianism and imperial social hierarchism.

Political philosophy seems to have fared differently compared with legal views and *siyasa*. It entered the Muslim purview along the Sassanian advice genre in the late eighth century onward and received courtly patronage most of the time but did not enjoy the popularity of either legal theories or *siyasa* genre. The pioneering translations from Greek into Arabic resembled more the advice literature and were circulated among court secretaries, although later it did not concern itself seriously with addressing ruling audience. This does not mean of course that the discussion of politics was solely theoretical. Politics emerged as a subsection of

the larger philosophical exposition on ontology, epistemology, and ethics, under the last of which it was studied as practical philosophy. Unlike Sunni theories, political philosophy envisioned political society as a natural and rational necessity emerging from the needs of human beings. They maintained that political society came into being step by step from the need of humans to live in a society, having laws and rulers to ensure steady and peaceful collaboration. Then philosophers theorized on ideal politics. A good illustration of this is the work of Farabi (951) who envisioned a perfect society (one of his political tracts is called *the Virtuous City*) under a philosopher-king.

Chinese Examination System in the Tang Dynasty

The civil examination system in China was more than just a test to determine qualified members of society for the civil bureaucracy. The government intended that the test serve several important social and political functions, including determining elite status within the empire, ensuring that the classic Confucian texts remain a vital part of Chinese governance, and using it as a method of creating an institutional elite who supported the idea of absolute power and as an attack on the hereditary aristocracy through the creation of a more fluid class of elites. The test thus represented the government's attempt to reorder the intellectual elite within China and to promote allegiance to the emperor at the expense of the powerful aristocratic families. The

success or failure of the various dynasties in achieving these goals depended on their ability to control the alternative means of entering the government outside the civil examination. While the Tang dynasty (618–906) was never able to fully prevent the hereditary elites from entering government service based on family origins, beginning with the Song dynasty (960–1279) the emperor was more successful in controlling the composition of the bureaucratic class.

Most scholars agree that the civil examination system originated in the Sui dynasty (589–617). The Tang, following their successful rebellion against the Sui, continued the system. The Tang viewed the system as a way of decreasing the power of the traditional aristocratic families in northern China. The Tang, however, failed to limit the yin privilege. The yin privilege allowed sons from high-ranking officials to enter the bureaucracy outside the civil examination system. It was only in the Song dynasty that the civil examination system functioned as the government originally intended. The Song closed alternative means of entering government as a means of moving more closely toward a merit-based system of choosing government officials.

Although all males in China were eligible to take the exam, in reality only those from wealthy families had the opportunity to pass the test. The nature of the exam, with its emphasis on memorization and orthodox readings of Confucian texts, required many years of study with tutors in order to confidently attempt the exam. This effectively prevented families that were not wealthy from preparing their sons for the exam. The exam consisted of five major categories, the most important of which were military strategy and the Confucian classics. The candidate had to compose strictly formatted essays that demonstrated a sophisticated understanding of the Five Classics and the other categories and their orthodox interpretations. The test varied considerably over time. At certain times poetry was an integral part of the exam, as the literati considered this skill an important part of Chinese culture. At other times the test focused more on skills that would aid the administration of the empire.

The test was theoretically intended to select qualified individuals for the bureaucracy, but its political nature cannot be understated. Emper-

ors viewed the test as a method of fostering loyalty among the officials for the emperor. Since the emperor often made the ultimate decision on who did or did not pass the test, the official naturally felt some loyalty for the emperor. Empress Wu (624–705) best exemplifies this. Empress Wu, who was viewed as a usurper by many officials when she came to power, increased the number of candidates placed into official positions in an effort to stock the bureaucracy with officials who viewed her reign more favorably. Although Empress Wu is an extreme example, every emperor was aware of the loyalty that the exam system created.

The examination system lasted from its advent during the Sui dynasty until 1905. The exam functioned, for the most part, as an effective method of choosing the most qualified candidates for government service, but there are some criticisms of the system. As mentioned earlier, the number of people who could dedicate the time and money to preparing for the exam was extremely small. While it is true that over time the exam decreased the power of the traditional northern aristocratic families, for the most part it merely transferred that power to other elite families. In addition, the test encouraged the study of specific texts and rewarded specific interpretations of those texts, which some scholars have criticized as contributing to limiting unorthodox thought and as a method that encourages homogenization. Despite these criticisms, there is no doubt that the civil examination system contributed to the stability of the Chinese bureaucratic system and allowed for some measure of social mobility.

SELECTION PROCESS FOR CANDIDATES FOR EXAMINATIONS

The government intended the exam to select the best-qualified candidates to fill positions. In order to do this they have to ensure that the testing process was as free from bias as possible. The Chinese took extreme measures to ensure the anonymity of candidates throughout the process. The testers provided each person taking the exam with a number, which they were to use in lieu of their name on their exams. In addition, because calligraphy was an art form in China, each test was rewritten by a third person. The rewriting of exams ensured that testers could not recognize the handwriting of the candidates. Despite these extreme measures, the testers were often charged with corruption. Many believed that the use of certain phrasing by candidates placed them within particular examination schools and therefore violated the anonymity the process promoted. Whether this was true or not, it remains clear that the Chinese went to extraordinary lengths to ensure that the best candidates were selected.

Ideological Legitimation of Imperial Power in Byzantium to 1000 CE

The early eastern Roman, or Byzantine, emperors inherited existing Roman ideas of power and its legitimation. Some of these derived from Roman law, especially the belief that the people had transferred its power to the ruler and the twin ideas that the prince was not bound by the letter of the law but was supposed to set an example by respecting its tenets. Another Roman inheritance was the military foundation of imperial authority, the heritage of Julius Caesar and other warriors who rose to power through military victories. Early emperors were called Augustus (for the first emperor) or *imperator* (literally “commander-in-chief”), the title accorded a victorious general in the early Roman Republic. To these Roman concepts were added Eastern elements as the empire became increasingly Greek. These included elaborate ceremo-

nial, bright robes, impressive throne rooms, and the Greek title *basileus* (king) that largely displaced the Latin titles originally in use. The Greek title *autocrator* (literally “one’s own master” or the one who rules by his own authority) was also used to claim unique power for the ruler. Christian elements, especially those derived from Constantine and his fourth-century successors, gave the emperor an air of sanctity and authorization by God. Theodosius I, who rose to power by appointment, was seen as vice-regent of God on earth; Leo III described himself as “the Vicar of Christ.” The title *isapostolos* (peer of the apostles) acknowledged the emperor’s special relationship to the Church in which he had a strong but not unlimited power. The ruler called Church councils and appointed bishops, including the patriarchs. This position of power did not exempt the ruler from accepting orthodoxy, and he was supposed to respect the patriarchs, especially the patriarch of Constantinople, the most important of the Eastern patriarchs and the chief rival to the bishop of Rome for first place in the Church.

The ruler nominally was elected but not in the modern sense of a political election. This election, or calling out, might be done by a reigning emperor (one’s father or other relative), who, following precedents from ancient Roman times, crowned his heir in his own lifetime; the army; the populace; or the Senate. (The populace could be fickle in this acclaim, as Justinian I learned during the Nike Riots of 532.) Whatever the source of an emperor’s election, all of the latter three were supposed to come together in the ceremonial entry of a new ruler into Constantinople through the Golden Gate. This ceremony was based on a Roman triumph, and the ruler was hailed as a victor over Rome’s enemies. The populace acclaimed the ruler, and the Senate (an assembly of notables with little other power) was expected to add its ratification. A coronation rite was introduced early, and the patriarch usually officiated. Only very late in the empire’s history was a rite of anointing, probably modeled on Western ceremonial traditions, added to this ritual.

The elective rites might be rendered unimportant if the emperor crowned his heir as co-ruler. Some rulers, especially those who rose to

Byzantine fresco depicting Emperor Constantine the Great (306–337 CE), from Karanlık Kilis, Turkey, twelfth century. The halo surrounding the emperor signifies the divine favor that the Christian ruler brings to the empire. (DeA Picture Library/Art Resource, NY)

► LEGITIMIZATION OF BYZANTINE IMPERIAL POWER

The Byzantine empire, like the Roman empire before it, had no strong sense of predetermined succession to the position of emperor. Emperors might be succeeded by their children or other chosen heirs, but usurpers could arise, usually from the armies. Those who were successful could be legitimized through acclamation by military commanders or approval by the Senate. Acclamation was a constituent part of the elevation of any emperor, reflecting the military origins of the imperial office. Eventually acclamation was supplemented with coronation by the patriarch of Constantinople, head of the Orthodox Church, the ceremony shifting from public places such as the Hippodrome to Hagia Sophia, the principal church of the capital. The legitimization of a usurper differed little in this respect from the accession of a legitimate ruler. The successful military usurper

held a triumphal procession into Constantinople, entering through the Golden Gate. (Victory was treated as a sign of divine favor for the usurper.) Public games and private celebrations accompanied the coronation, while a genealogy might be forged, as in the case of Basil I in 867, to buttress the new regime. Marriage into an existing imperial line was also useful. John Tzimisces married a daughter of Constantine VII after his coronation in December of 969 in a bid for legitimacy. Tzimisces also humbled himself before the patriarch of Constantinople. Tzimisces had murdered his uncle, Nicephorus II, himself a usurper, who had both married the widow of Romanus II and become guardian of his children. These children eventually succeeded as Basil II and Constantine VIII.

—Thomas M. Izbicki

power as military leaders, deposing and killing off a former emperor, often gained legitimacy by marrying into an existing imperial line, wedding an heiress or a widowed empress. Co-rulers were sometimes recognized when an heir was a minor, and an adult might be crowned to rule until the heir reached maturity. All of these factors are illustrated by the minority of Basil II. Nicephorus II Phocas married the widowed Empress Theophano, Basil's mother. John I Tzimisces, who murdered Nicephorus, was forbidden to wed his widow, so he exiled her but kept Basil and Constantine, his brother, until his own death. Only then did Basil and Constantine take power together. In some other minorities, the mothers of young rulers served as regents. The Empress Irene decided to retain power by deposing and blinding her son, Constantine VI. However, the new emperor came to power, and he accepted the robes and pomp of office, dazzling visitors with the majesty of the New Rome. His reign was expected to last until death, but death could come early through war or murder. Other rulers were deposed and mutilated, usually—as Constantine VI was—by blinding to prevent their regaining power. Titles and ceremony did not protect the emperor from the hazards of holding power.

Church, Army, and State in Byzantium

The interaction among the emperor, the army, and the Orthodox Church created a swirling political dynamic in Byzantium from the inception of the eastern empire in the fourth century through the beginning of the thirteenth century. Emperors and empresses needed an army made loyal through good pay or choice land and played church factions against each other, always with an eye to the army's reaction to the religious controversy. More than once, an emperor or a theologian put forward the idea that the political realm (*imperium*) and the religious realm (*sacerdotium*) represented parallel commissions from God, one to care for bodies and

Emperor Justinian I and his retinue of officials, soldiers, and clergy. Church and state in the Byzantine empire were intimately entwined. The Byzantine emperor was supreme and regularly appointed and deposed bishops and other church officials. (Archivo Iconografico, S.A./Corbis)

the other to care for souls. In the case of Byzantium, however, parallel lines often met.

In the fourth century, Constantine saw the advantage of a united Christian Church and used the political means at his disposal against dissension. Less noticed but perhaps as important as his willingness to banish an uncooperative bishop was his sending of imperial troops against a group of North African schismatics, the Donatists. From the beginning, then, emperors would use the army to end church controversy if necessary. Constantine was also the first to support the Church through a building program, a primary way of exercising influence in the ancient and medieval worlds. The emperors after Constantine further tightened the relationship between Crown and miter by turning the power of law against non-Christians, whether Romans, Greeks, or Jews. Constantine's sons initiated the practice, and in the fifth century Theodosius further encoded it into law. The greatest example of legislating on behalf of the church is Justinian's work in the sixth century, whose reign marks the closest relationship between church and throne. Justinian was determined to root out paganism and, for example, banished the philosophers from Athens in 529. In an attempt to reconcile the still smoldering Monophysite controversy, he also called the fifth

ecumenical council, that of Constantinople, in 553. As the preceding examples show, the emperor acted in church affairs by calling councils and exiling bishops. Often motivated by political agendas, imperial assertiveness in theological controversy at times caused the convocation of an ecumenical council that reversed imperial positions. The quasi-clerical privileges enjoyed by the emperor complicated matters. So, for example, the emperor could enter the church sanctuary, but the laity could not. He also received the Eucharist in the same manner as the priests, could bless the congregation, and could even preach, which Leo VI frequently did.

Imperial endeavors in doctrinal matters sometimes led to more serious upheavals. Heraclius's (d. 641) attempt to resolve the monothelite issue (a failed compromise between Monophysites and diophysites) with his *Ecthesis*, supportive of monothelitism, in 638 was met by the opposition of Maximus the Confessor, who in 646 in North Africa preached so effectively that Gregory of Carthage proclaimed himself emperor. His attempted usurpation was crushed as soon as it began, however, by the advancing Arab empire. The intrigue continued as Constans II sent Olympius to arrest Pope Martin of Rome, who not only opposed monothelitism but also took the papacy without imperial approval. Olympius, however, chose to revolt and separate Italy from Constantinople. He also failed, and the pope was brought to Constantinople for trial. The iconoclastic controversy also showed the intimate connection between church and throne. Emperor Leo III, attempting to control the church and centralize the state, forbade the worship of images in 725. Empress Irene, however, pressed for the Second Council of Nicaea, the last of the Seven Ecumenical Councils, that met in 787 and fervently defended the use of images. A century later, the *filioque* controversy left Ignatius and Photius, competing patriarchs of Constantinople, with alternating periods of royal support.

From the time of the first great doctrinal controversy, Arianism, and the first ecumenical council at Nicaea in the fourth century, the power of the monks to influence the people had to be taken very seriously. Later, from the eighth through the tenth centuries, monasticism was a

force to be reckoned with economically and politically as well as doctrinally. Monks stood to lose the most in the eighth century when Leo III sought to outlaw images, and they resisted him fiercely. In addition, the monasteries had acquired large tracts of tax-exempt land, and their lifestyle often seemed anything but impoverished. When the plague reduced Asia Minor's population by a third in the mid-eighth century, Constantine V Copronymus's anger raged against them not only for their worship of icons but also because monasticism represented the loss of so many able-bodied men from the army and the economy. As the iconoclastic controversy continued over the next century, leading monks insisted that the emperor did not transcend divine law, and their disdain did not stop there. The moechian (from the Greek word for "adultery") controversy at the end of the eighth century pitted Constantine VI against them. The conflict, along with tensions over images, continued into the next century, led by the formidable opposition of the famous monk Theodore the Studite.

An objective of imperial ecclesiastical policy was the loyalty of the military. Heraclius and Constans II saw revolts arise around their monothelite agendas. Constantine V had a similar hatred for all things associated with icons that also was born from military conflict. He had been defeated by his brother-in-law, the iconodule Artavasdos. Upon repairing to iconoclastic Anatolia, Constantine found men at the ready to join him in renewed attack on his nemesis. When Constantine defeated Artavasdos and took the throne in Constantinople, he had learned two things. The first was an even more visceral antipathy toward icons that led him to persecute monks viciously, and the second was a lesson in the strength of those who venerated icons. Yet this was also a man who wrote at least 13 theological treatises and perhaps held his iconoclasm with some sincerity. Later, the empress Irene, who restored the use of icons upon assuming the throne, put down a revolt of the overwhelming iconoclast Anatolian Army. She then attempted to purge the army of iconoclast foes but succeeded only in generating more rebellion.

The success or failure of imperial military expeditions was often seen as a sign of divine

favor or disapproval. Heraclius supported his monothelite initiative by appealing to his victory over the Persians, and Leo V interpreted military defeats as God's punishment and advanced iconoclasm as the cure. Leo was not alone in this opinion. The army and the Constantinopolitan aristocracy also looked at the military success of iconoclast emperors and the defeat of iconodule rulers as God's judgment on the issue. Leo made no secret of his desire to placate his warriors, and the decree of the episcopal synod that he convoked in 815 stated plainly that the empire did well until a woman (Irene) took the throne and restored the veneration of images.

Maintaining the army's loyalty was critical to the emperor's power, and pay was often at the heart of the issue. Military pay was problematic from the time of Diocletian due to inflation and shrinking revenues. As imperial lands shrank from the sixth through the eighth centuries, Persian and then Arab conflict did not permit a proportional reduction in the size of the army. In 602, Emperor Maurice was deposed and executed by Phokas, a military leader at the Danube whose troops already had ceased their loyalty in the face of military economizing. Heraclius, his successor by yet another rebellion, cut pay again, although he was able to maintain loyalty and defeat the powerful Persians. The army was reorganized in the seventh century into units called themes and later into tagmata. By this time the practice of paying the soldiers with parcels of land had rendered the army sufficiently self-supporting to enable ambitious commanders to mount frequent revolts. On the other hand, now that soldiers had their own land, probably former imperial estates, they had incentive to defend the borders valiantly. Constantine V's creation of the tagmata helped slow the revolts. His rival Artavasdos was leader of the Opsician Theme. Constantine divided this formidable and often mutinous force into three units called tagmata. Their increased mobility provided tactical advantage, and resulting victories increased their loyalty to the emperor. Continued victories and reconquered territory provided both wealth and men to expand the military, which it did somewhat robustly from the eighth through the tenth centuries, especially toward the end of the

tenth century. By the start of the eleventh century, the state treasury enjoyed a large surplus. Through the ninth century, the emperors and the army became more closely allied, and the emperors often named Anatolian aristocrats to military posts. Not only were such men the most capable leaders, but they also shared the imperial interest in military might.

The tenth century saw the ascent of John Tzimisces to the throne. It was he who remarked that God had entrusted souls to church and bodies to empire, another way of saying what Constantine and Eusebius had said at the outset of the eastern empire. Orthodoxy, and consequently Byzantium, saw the human experience organically. Church and state *were not* separate because both were reflections of God's divine governance of all that exists through God's having created it. Church and state *were* separate because both had

distinctive realms over which they ruled. In either case, the army mattered greatly.

■ Introduction: Sub-Saharan States

The Nubian kingdoms were the most venerable states in Africa south of the Sahara. They developed out of the ancient civilization of Kush. The two Christian Nubian kingdoms and Allodia, situated on a 600-mile stretch of the Nile River south of Aswan, were, like their Kushite predecessors, culturally connected with the Mediterranean world and maintained their independence for nearly 1,000 years.

Ethiopia was another African state with roots in the classic era. In the first part of our era, Axum, as Ethiopia was then known, flourished as an important anchor for the African trade with India and the Mediterranean, but after 650 CE, defeats by the Muslim Arabs drove the Axumites from the coast to the Ethiopian highlands, where they developed their unique medieval Ethiopian civilization.

In the grasslands of the western Sudan, the development of camel-borne trans-Saharan trade with the Mediterranean region stimulated the emergence of the empires of Wagadu (Ghana) and Kanem. Wagadu, located north of the upper Niger River, is thought to have emerged about

the fourth century CE, while Kanem, situated near Lake Chad, was much younger than Wagadu, arising probably not before the eighth century.

In the forested areas of West Africa, small city-states were emerging in this period. Ife, the mother city of Yoruba land, was one of the most important of these, but there were others such as Igbo-Ukwu, which was the capital of the shadowy Nri kingdom that dominated the Igbo (Ibo) people. This was the springtime of city-state building in the Guinea forest. For a stretch of the West African forest extending through the Niger Delta and westward for more than 1,000 miles independent city-states were emerging by the middle of this period (700 CE).

On the Swahili coast of East Africa another group of city-states emerged in the latter part of this period. In response to the stimulus created by increasing Indian Ocean trade, coastal Bantu villages grew into wealthy cities, of which the Lamu archipelago island cities, Shanga and Manda, were most important. These cities were independent states ruled by native kings.

Throughout Africa south of the Sahara, the period 300 to 1000 CE witnessed a steady increase in population as a result of the introduction of Asian crops. By the end of this period, Africa south of the Sahara had reached a population density sufficient for the creation of small kingdoms throughout the region. That would take place in the subsequent era.

Africa's Role in Early Medieval World History

While Westerners are tempted to view African culture and history in monolithic terms, experts in African studies point to the enormous diversity that Africa presents. It has been said that there is as much diversity among, for example, the Tuareg of the Sahara Desert, the Ibo of the Nigerian cities, the merchants of the Swahili coast, and the Ba-Twa hunter gatherers of the equatorial forest as there is in the whole of the Afro-Eurasian ecumene, which includes Europe and North Africa, as well as West, East, South, and Southeast Asia.

The greatest divider in African historical geography is the vast Sahara Desert that, as effectively as a great ocean, isolated Mediterranean Africa from the lands to the south of the great desert. Culturally and historically, Mediterranean Africa was part of the Afro-Eurasian ecumene, the collective of interacting peoples that spanned the Eastern Hemisphere, diffusing technologies, religions, mythologies, and folkways. African peoples south of the Sahara were, for the most part, cut off from the ecumene and had the freedom to develop in their own solitudes.

However, in the early medieval age, contacts with the Afro-Eurasian ecumene began to grow and produce changes in both western and eastern sub-Saharan Africa. When, in the early centuries CE, the Berbers of North Africa acquired

camels, camel nomadism spread throughout the Sahara Desert; by 300 CE, trans-Saharan trade developed apace, stimulating the formation of kingdoms and then empires in the grasslands south of the desert. By the mid-seventh century, Berber merchants, newly converted to Islam, brought their religion to the new trading cities south of the desert. In time, but mostly after the first millennium CE, the population of the western Sudan became Islamized and influences from north of the Sahara began to infiltrate the region. But these influences disseminated much more slowly to the forest peoples south of the western Sudan who continued to develop according to their internal dynamics.

In the eastern horn of Africa, a different narrative unfolded. The Nubians on the Nile as well as in the Ethiopian highlands had for centuries been influenced by Mediterranean culture. They converted to Christianity early in the medieval age, but the proof of their resistance to external influences is that the Muslim wave was unable to convert them until after this period. Even today, many of the Ethiopian peoples remain Christian. From 300 to about 650 CE, the Ethiopians were intimately involved in oceanic trade, sailing to India and to Egyptian ports on the Red Sea coast. But when the Muslim Arabs seized control of Indian Ocean trade, the Ethiopians withdrew to their highlands and hermetically sealed themselves from foreign experiences.

The external currents that most radically changed much of sub-Saharan Africa during the first millennium CE emanated from Indonesia and Southeast Asia and were carried on the crafts of the Austronesian settlers of Madagascar. These Austronesians brought with them Southeast Asian crops and culture: sugar, rice, Asian yams, and taro as well as many other crops, though the most important crop was bananas. The Austronesians who brought these crops to Madagascar also apparently brought them to the East African coast, where the coastal peoples eagerly cultivated them. Over the centuries, these Asian food crops spread from people to people, until by about 1000 CE, most of the peoples in the forested parts of the great lakes region, the equatorial forest, and forested West Africa relied on them for the bulk of their food. These new sources of abundant nutrition, especially

bananas, produced a population increase that led to larger settlements and the formation of states and kingdoms.

The histories of sub-Saharan African peoples are only now being pieced together, whereas the histories of Mediterranean African peoples during the early medieval age are well documented. Most of the sub-Saharan peoples preserved their histories orally, often by a group of specialists who served as official rememberers. But in the nineteenth and early twentieth centuries the catastrophe of European conquest destroyed many sub-Saharan African states, devastated their culture, and disrupted their traditions. Such a situation causes great difficulty in

reconstructing the pasts of those who were once thought of as people without history.

—Wilfred J. Bisson

West Sudanese Empires

In the broad area south of the Sahara Desert and west of the Nile Basin, two areas became the focus of large-scale state building after 300 CE. In the far western part of the area two rivers, the Senegal and the Niger, provided the economic and transportation base for the political developments. Farther east, the development was more focused because the Chari-Logone river system

empties into Lake Chad, which became the sole major focus of state building.

North of the Senegal River, the Soninke empire of Wagadu arose about the third or fourth century CE. The ruler of the empire was called the Ghana, and historians have often used that name for the empire as a whole. The empire was created when a number of smaller localized states were absorbed by the growing power of the Soninke.

The driving economic force behind the empire was the renewed trade across the Sahara. Two things sparked this renewal for trade: the products and the means of transport. The camel had been introduced by the Berbers of North Africa in the third or fourth century. Wagadu was able to control the trade in gold and salt. The source of the gold was located in Bambuk and Bure to the south of Wagadu. The source of the salt was Taghaza. Neither source was located in the empire, but control of these goods was essential for controlling the trade and providing the taxes necessary for the empire.

Wagadu reached its zenith of power in the ninth to eleventh centuries, at which time its main trading partners were Muslims from North Africa. The capital of Wagadu, Koumbi-Saleh, consisted of two cities separated by a road six miles long according to the Arab historian al-Bakri. Koumbi was the location of the palace of the king and where the Soninke lived. Saleh was where the Muslim traders lived. It contained 12 mosques. The separation was an indication of the ambivalence of the Ghana toward his Muslim guests.

The Soninke were matrilineal, and on the death of the Ghana his sister's son became the new Ghana. The royal palace was located within a grove of trees in the middle of Koumbi. The ancestral rulers were buried in the forest, indicating that the Ghana was at the center of a still powerful Soninke religion. It was perhaps because of the strength of the indigenous religion and culture that the Ghana never fully accepted Islam and attempted to keep the Muslims at a distance.

The decline of Wagadu began with a conflict between the Soninke and a Muslim reform movement, the Almoravids or Al-Murabitun. The Al-Murabitun was a warlike movement focused on purging Islam of recent heresies. They came

➤ A USABLE GENEALOGY AND A NOTE ON DATING

By the time of the contact between the empire of Kanem and the Muslim world in the 800s CE, the Abbasid revolution had already taken place. It became important for the rulers of Muslim states to establish their proper credentials to rule the country. These credentials were defined as Shari-fian descent. That is, to be the ruler of a Muslim state one should be able to trace one's descent from Muhammad.

During the initial period of contact with the Muslims the Mai or ruler of Kanem was not required to be Muslim, nor did it matter to the Mai. After some centuries of contact this requirement became important, but a problem arose. If the line of the Mais only stretched back to the 700s CE, then there were multiple appropriate male founders available. The line could be connected to the line of the Prophet via a mythical concubine who had a son with Muhammad, Ali, Hasan, Houssein, or others, so we must ask why that connection was not claimed. The answer must be that it was not believable. It was not believable because the people of Kanem knew that the kingdom was already established before the Prophet was born.

To resolve that issue the Muslim scholars in Chad found an ancestor who lived in the proper period and filled most of the conditions, Sef or Saif ibn Dhi Yazan. Later, as time passed, the oral historians of Kanem gradually forgot the names of lesser rulers, much like people today do not remember the names of obscure presidents yet still know that the United States was founded in 1776. In this way the remembered rulers when finally recorded in writing only stretched back to the 700s.

—Douglas E. Saxon

into conflict with the Soninke in 1062. According to sources from the period, the Ghana could field an army of 100,000 knights. The war lasted several years, and according to tradition the Al-Murabitun eventually defeated the Soninke. Wagadu declined in power, and its constituent states began to fight for control of the trade.

In the middle to latter half of the sixth century CE the kingdom of Kanem was founded northeast of Lake Chad. The people of Kanem, speakers of a Saharan language, had been spreading to the south and west for centuries

after the northern section of Lake Chad dried out. As the lake dried out the people gradually shifted to a more nomadic lifestyle based on cattle herding. They encountered a settled people who had been living in cities since the last millennium BCE. These interactions come to us as the myths of the So or Sao, whom the people of Kanem described as giants possessed of superhuman strength and powers. Over centuries of trade, warfare, and intermarriage the people of Kanem settled and established an agricultural state.

The first Mai or ruler of Kanem was called Sef and was reputed to be Saif ibn Dhi Yazan from Arabia. His capital was established at Njimi. The state followed the typical Sudanic model. The ruler was regarded as divine and the leader of a state sect that was focused around a relic called the mune. In the thirteenth century conflicts between the local religion and Islam would have major consequences for Kanem, but during this period there were no problems like those faced by Wagadu farther west. For the early rulers, frequently all that is known is the clan of their wives, indicating the importance of that connection and a relatively important position of women in the society.

By the late 800s Kanem was in contact and trading with the Muslim Khariji emirates in North Africa. This is the date of the first contact between Kanem and Islam. The Khariji, or Kharijites, were heterodox Muslims. Mosques built in Kanem dating to this period use a peculiar type of minaret called a staircase minaret, unique to the Kharijis. There are also reports that merchants living among the Khariji were able to speak the language of Kanem because of their trade activities. By the end of the first millennium CE, the Mais of Kanem had converted to Islam.

In this area the major trade item was slaves, who were traded for salt and other goods. By 909 CE the Kharijis were replaced by the newly established Shia Fatimid state, which continued the trade. Throughout the remainder of the period to 1000 CE Kanem continued to grow and prosper, developing a large slave-trading network to the south and continued connections to the north. The height of power would be reached in the thirteenth century under Du-

nama II Dibalami, who extended the state into the desert as far as the oasis of Bilma.

Ethiopian Political History

In the fourth century a vigorous African state, known to us as Ethiopia, prospered through controlling the trade of the Red Sea, the southern end of which it dominated. The center of this state was the town of Aksum by which the state itself was commonly known to its contemporaries. Aksum exported gold, ivory, tortoiseshell, rhinoceros horn, and slaves and imported brass and copper objects, iron bars, and weapons. Aksum was firmly rooted in a highland plateau, the edge of which is close to the coast. The rulers of Aksum spoke Geez, a Semitic language closely related to the languages of South Arabia, which, in turn, are related to the Arabic of the Quran. One of Aksum's achievements was a distinctive script, which is still in common use. Most of the subjects of Aksum were farmers, who used plows drawn by oxen to grow a wide variety of crops and probably also spoke Semitic languages. Aksum's dominion and the people under it were diverse in culture and language. Some of its subjects spoke Kushitic or Nilo-Saharan languages (ancestors of languages such as today's Somali or Nubian), and some were pastoral herders of cattle, sheep, and goats.

"Ethiopia" is a term that Greek-speaking people used to refer to the black people of Africa. The wider trading world in which Aksum participated was dominated by Greek-speakers. The first record that a ruler of Aksum used the term "Ethiopia" to refer to his own country is an inscription, written in Greek, that probably dates to the third century CE. The term "Ethiopia" appears to have been the Greek translation of the

Geez “Habasha.” By this time Aksum was mentioned as one of the four kingdoms of the world, the others being Rome, Persia, and Sileos. Its rulers commonly referred to themselves, on the coins they issued and the monuments they erected, as “King of Aksum,” the monuments also claiming authority over the territories and peoples on both the African and South Arabian sides of the Red Sea. The rulers of Aksum erected numerous carved monoliths and monumental thrones and built palaces of stone.

We know the names of some 20 rulers of Aksum who, from about 270 CE to about 740 CE, issued coins in gold, silver, and copper. However, much of the information concerning Aksum clusters around the reigns of two kings, Ezana, of the second quarter of the fourth century, and Kaleb, of the early sixth century. This information comes, in addition to the coins, from archaeology, their inscriptions on stone monuments in three different languages (Sabeen, Geez, and Greek), the traditions of later generations, and a handful of accounts by contemporary travelers, historians, and geographers. Ezana’s inscriptions describe in some detail campaigns in Ethiopia and into the Sudan. Ezana referred to himself both as “king” and as “king of kings,” titles used by rulers of Ethiopia into the twentieth century. He is most famous as having adopted Christianity sometime around 340, the religion followed by his successors and, eventually, the faith of many of the subjects of the Ethiopian kings.

Kaleb, Ezana’s eventual successor, is noted for having championed Christianity, founding churches in Ethiopia and protecting the Christians of South Arabia on whose behalf he waged war. Toward the end of the years separating the reigns of Ezana and Kaleb, Ethiopian tradition records the arrival of two groups—the Tsadqan (“the Holy Ones”) and the Nine Saints—who contributed greatly to the spread of Christianity in Aksum by founding monasteries and churches. Kaleb’s period may also have seen the founding of the Ethiopian church’s musical tradition and the translation of the Bible into Geez. Religion was but one dimension to the struggles over South Arabia. Kaleb was allied with the ruler of Byzantium in a struggle against Persia to control the trade from Asia to the eastern Mediterra-

Hewn from a single granite stone in the fourth century, the most famous obelisk in the ancient city of Aksum commemorates the reign of King Ezana. (UNESCO Photobank/Maureen Dunne)

nean. In the short term the Persians were victorious, expelling the Aksumites from South Arabia. In the long term the struggles of these three powers were transformed by the rise of Islam, founded in the years 622–632 at the holy sites of Mecca and Medina, just across the Red Sea from Ethiopia, and the creation, by 700 CE, of a great Arab empire based at Damascus. Most important for the Aksumites was Arab naval control of the Red Sea, which appears to have been complete by about 750, a date that marks the

➤ EZANA'S CONVERSION TO CHRISTIANITY

Ezana's conversion to Christianity is one of Aksum's best-documented events. It is attested to by monumental inscriptions, coins, contemporary foreigners, and Ethiopian traditions. The inscriptions invoke three distinct religious languages. First, they referred to Ezana as "the son of Mahram" (in Geez; "Ares" in Greek), the South Arabian god of war. A transitional inscription uses monotheistic language referring to "the might of the Lord of Heaven" and "the Lord of all." Finally, an inscription discovered in 1969 starts, "In the faith of God and the power of the Father, and the Son and the Holy Ghost who have saved my kingdom. I believe in Your Son Jesus Christ." This same progression, from South Arabian religion through monotheism to Christianity, is also evident from Ezana's coins. Some are inscribed with the South Arabian crescent and disc, while others are inscribed with a cross. The crescent and disc appear on the coins of all his predecessors, and the cross appears on the coins of all his successors.

Two literary sources date the conversion. Rufinus, a Church historian (345–410/411), told of Frumentius (remembered in Ethiopian traditions), who converted an unnamed king and was then consecrated bishop by Athanasius, patriarch of Alexandria (325–373), to serve that same king. Emperor Constantius of Constantinople (337–361), an enemy of Athanasius, wrote a letter to Ezana asking him to send Frumentius back to Alexandria for instruction in the true faith. These sources indicate that Ezana's conversion, which profoundly shaped the future of Ethiopia, took place around 340.

—Donald Crummey

definitive decline of the empire, whose rulers then stopped issuing coins. Islam slowly established itself among the peoples of the Ethiopian coast and eastern lowlands.

Losing control of the Red Sea trade was a devastating blow to Aksum, which now proved unable to protect its northwestern borders from incursions by the Beja people. Sometime after 750 crude inscriptions in Aksum record revolts of people on the southern borders suppressed by a ruler called Hatsani Daniel. Environmental factors also undermined the empire, which had

emerged in the first century of the Christian era on a wave of agricultural prosperity associated with an increase in rainfall. However, by 650 there is evidence of increasing soil erosion, which, after 700, became catastrophic, and in the earlier eighth century rainfall began to decline drastically.

The Aksumite empire slipped into international obscurity at the same time as its culture, political traditions, and church found new leases on life in territories to the south. Already in the reign of Kaleb, the governor of the Agaw, a Kushitic-speaking people living some 124 miles (200 kilometers) south of the heart of the empire, was important in controlling the gold trade. Aksum, as capital, was replaced by Kubar still farther to the south. Aksumite outposts spread agricultural techniques, Semitic language, and Christianity, giving rise, out of an earlier population of Agaw-related peoples, to the Amhara, who from the thirteenth century onward were to dominate Ethiopia. Success in the spread of Semitic culture and political domination is indicated by the rebellion in reaction to these processes, around 950–960, of a queen of Damot, a territory as far south as modern Addis Ababa. The revolt destroyed many churches and is vividly remembered in local traditions across northern Ethiopia. Aksum's legacy survived this reversal and bequeathed to later generations of Ethiopians an indigenous church, a script, Semitic language, and political traditions.

The Political and Social Formation of Swahili Civilization

Like all African civilizations, the beginnings of the Swahili-speaking people of East Africa's

coast are rooted in myth. Traditional Swahili explanations of their origins usually begin with stories of migrations of the so-called Shirazi or the Wadebuli or other Arabs to the coast sometime around the tenth century CE. Scholars long have pondered the historical accuracy of these accounts, asking when the actual origins of Swahili urban civilization were and just who these mysterious founders might have been. A few tantalizing literate accounts by Islamic scholars throw additional light on these questions; some of our best evidence comes from archaeological and linguistics research. While no single type of source by itself provides an adequate picture, taken together they provide a reasonably detailed representation of the early formation and character of Swahili communities.

Scholars agree that the places of origin usually claimed by the Swahili for their founding ancestors can be identified with Persia (Shiraz) or northwestern India (Debul). For many years, Western scholars accepted such legends at face value, believing that sometime during the period of the Abbasid caliphs groups of Muslims migrated to East Africa and founded Swahili cities such as Lamu, Mombasa, and Kilwa as foreign Arab communities that had little in common with their neighbors of the African interior. Archaeological and linguistic research over the past three decades, however, has challenged that viewpoint. Although the Swahili have been majority Muslims for the past seven centuries, their ancestors clearly were not Islamic migrants who had arrived from elsewhere in the western Indian Ocean. Rather, they primarily are descendants of African Bantu-speaking peoples who originated in West Africa and spread rapidly through the rain forests and savannas of central Africa, arriving on the coast of what is now Tanzania in the early centuries CE. These were primarily animist, village-based farmers who lived off a diet of cereals, yams, and livestock. Like their Bantu-speaking neighbors, their primary unit of social organization would have been the clan. In the centuries that followed, these peoples expanded northward along the coast and its hinterlands until around the eighth century when they began to split into discrete ethnic and (related) language groups, one of which included the ancestors of today's Swahili speakers.

*Excavation of a mosque at Shanga, from 780 CE.
(Mark Horton)*

One can assume that during these centuries political organization probably never exceeded anything larger than small chieftaincies. Political power was diffuse, with clan elders exercising considerable influence and being capable of overriding any chief in both executive and judicial decision making.

This process of expansion was accompanied by significant cultural change as these ancestral Swahili speakers adapted to new opportunities presented them by the coastal environmental niche in which they now found themselves. Again, both archaeological and linguistic data indicate that the old economy based on mixed cereal and yam farming expanded to include new crops that thrived in the coastal soils and heavier monsoon rains, such as coconut, mango, bananas, and rice. Villages at various locations such as Mogadishu on the Somali coast and Shanga and Manda on the coast of Kenya grew into larger and, probably, more socially stratified towns in which there was a larger variety of economic activities, some of which, such as crafts production and commerce for example, came to attach greater status to their practitioners. Most significant perhaps is that such communities became increasingly influenced by the world of the western Indian Ocean and new vistas provided by marine activities that supplemented long-established agrarian ways of life in terms of both avocation and diet. Well before the end of the first millennium we find evidence of an economy based as much on fishing the abundant marine life found

THE TRADITION OF THE COMING OF THE SHIRAZI FROM THE KILWA CHRONICLE

“When [the Shirazi] arrived in a ship, they went to Kilwa, they found it was an island, but that at low water it was joined to the mainland so that one could cross on foot. They disembarked on the island and met a man who was a Muslim. . . .

“They asked the Muslim about the country and he replied: The island is ruled by an infidel from Muli, who is king of it; he has gone to Muli to hunt, but will soon return. After a few days the infidel returned from Muli and crossed to the island at low tide. The newcomer and he met together and [the Muslim] acted as interpreter. The [Shirazi] newcomer to Kilwa said: I would like to settle on the island: pray sell it to me so that I may do so. The infidel answered: I will sell it on condition that you encircle the island with coloured clothing. The newcomer agreed with the infidel and bought on the condition stipulated. He encircled the island with clothing. . . . So the infidel agreed and carried away all the clothing, handing over the island and departing to Muli.”

—Randall Pouwels

in offshore reefs and mining their corals for building materials as on cereals and domestic stock. Moreover, Bantu skills in iron making and African animal by-products soon attracted the interest of ship captains, who availed themselves of monsoon winds to pay yearly visits to the coast to trade. Since winds as well as coastal currents favored ports of call north of Zanzibar, not surprisingly it was towns on the southern Somali and Kenyan coasts that were the first to experience the transformational effects that such trade would have had on the coastal Bantu civilization. Well before 1000 communities such as Mogadishu, Shanga, and Manda were becoming specialized in crafts and commodities production for export as well as serving as conduits for luxury imports.

Iron and ivory along with animal hides, rhino horn, and ambergris were the principal exports, while ceramic wares, dates, and Indian cloth and beads were the items most in demand by African producers and merchants.

The late first millennium also saw the introduction of Islam among the ancestral Swahili. Archaeologists have excavated mosques and Islamic burials at Manda and Shanga as well as in Zanzibar and Pemba, dating from the eighth century, and a tenth-century source mentions the presence of Muslims at Qanbalu, most likely Pemba. It is virtually certain that these first Muslims were immigrants. Nevertheless, the prestigious association of Islam with international trade both attracted converts and contributed to the partial Islamization of urban political institutions and social values almost from the start. Gold, silver, and copper coins minted in the name of a ruling dynasty at Manda and Zanzibar provide evidence of a Muslim sultanate by the tenth century. Ultimately, the most transformational effect that Islam had on coastal society resulted from the introduction of literacy, particularly from written law (the Sharia). Whereas African ideas about social rights and legitimacy typically originated in claims of kinship, ethnicity, and oral traditions that supported them, the Sharia applied universal laws. African customary law usually granted greater rights to women in matters of property, inheritance, and marriage than the Sharia allowed. A proper interpretation of the Shirazi origin myths was therefore as a story that established the primacy of the Islamic cult and of Islamic written traditions concerning marriage, the (reduced) rights of women, inheritance, and property over African customs.

Nubian Kingdoms, 350–1000 CE

The Christian Nubian kingdoms of Makuria and Alwa (Alodia) existed as prosperous states on a 600-mile stretch of the Nile River (in present-day Sudan) from the early sixth to the late fourteenth centuries.

Before its conquest by the Mamluks of Egypt about 1350 CE, the area on the banks of the Nile River in the northern half of what is today the Republic of Sudan is referred to as Nubia. This area on the Upper Nile had long been influenced by Egyptian civilization and had developed its own remarkable civilization along parallel lines. From about 1000 BCE until its overthrow, in circa 350 CE, the Kingdom of Kush (Cush), with its capital of Meroe, ruled this region.

Egypt was a province of the Roman empire until 641, and the boundary between it and the Kingdom of Kush was, until around 300 CE, about 160 miles south of modern Aswan. At around 300 CE Roman forces retreated to the fortress of Philae, just south of Aswan. The Romans moved the Nobatai, a people who had dwelt in the Great (or Kharga) Oasis, into the territory they vacated. Known as *foederati*, the Nobatai were bound by treaty to guard the Roman frontier. These Nobatai were the ancestors of the Nubians.

Ezana, the ruler of the powerful Ethiopian kingdom of Axum, destroyed Meroe circa 300 CE. To commemorate this victory, the Axumites erected a stone stele on the banks of the Nile River, where it still stands. After the destruction of Meroe and with it the Kushite state, the Nobatai and a nomadic group, the Blemmyes, contested for the territory of the defunct state. The wars between these two peoples continued for much of the fifth century, until the final defeat of the Blemmyes by King Silko, perhaps about 575 CE. Silko was ruler of Nobadia, an early Nubian state that was absorbed into Makuria in the sixth century.

The language of Kush disappeared with its political power, to be replaced by that of the incoming Nobatai. Their language, Old Nubian, became the language of the people as well as the administration and often the Church, although the liturgical languages were Coptic and at times Greek.

CHRONOLOGY OF CHRISTIAN NUBIA

Late fourth century: Collapse of Kush invasion of Nubia by Nobadia; emergence of state of Nobadia.

Fifth century: Wars between Blemmyes and Nobadia.

Early sixth century: Emergence of kingdoms of Makuria and Alwa.

Mid-sixth century: All Nubian kingdoms adopt Christianity.

Early seventh century: Absorption of Nobadia by Makuria.

Mid-seventh century: War between Makuria and Muslim invaders from Egypt; negotiation of *Baqt* or Truce that was to last 600 years.

Late fourteenth century: Conquest of Makuria by Muslims.

Mid-sixteenth century: Final conquest of last Nubian kingdom by Muslims.

—Wilfred J. Bisson

Nobadia, the first Nubian kingdom, rose in the late fourth century and existed as the sole Nubian kingdom for the next century, but its authority extended only over the northern third of the territory ruled by Nubian groups. Makuria and Alwa, the other two kingdoms, emerged in the early sixth century.

The early medieval history of Nubia begins with the conversions of the three kingdoms to Christianity in the mid-sixth century. The first Christian missionaries were from the Egyptian Coptic Church, but rival Greek Orthodox missionaries from Constantinople shortly joined them. In the early years, considerable friction developed between the two faiths, and this produced contention among the three kingdoms. However, their populations readily embraced the new faith, as far as we can know from the record.

Within a generation, most Nubians were members of the Coptic Church, whose spiritual head was the patriarch of Alexandria, Egypt. Impressive brick churches were built in all the Nubian cities, and the Christian clergy assumed a position of leadership in Church and state. In

Nubian popular Christianity, the archangel Michael was very prominent, playing a role similar to that of St. George the dragon slayer in medieval European Christianity.

Both Makuria and Alwa were ruled by a series of royal dynasties. Usually, the royal families of the two kingdoms intermarried. Succession to the throne was by uterine descent; the son of the reigning king's sister inherited the throne. Since the kings of Makuria and Alwa were often married to each other's sister, their sons were often heirs to their brother-in-law's kingdom. We can only speculate about the fate of the royal family on Nobadia after its absorption, either by conquest or dynastic marriage, into the kingdom of Makuria. Nobadia became the Makurian province of Maris and guarded the northern frontier. After the Muslim conquest of Egypt, the Makurian official governing Maris occupied an extremely sensitive post. This official, whose title was eparch, was usually a member of the royal family.

Except in the northern province of Maris, Makuria was ruled by 13 kinglets, all of whom were priests under the hegemony of the king. The king, at least theoretically, owned all land and had the power of reducing anyone to slavery for any reason.

Dongola, nearly 100 miles north of the great bend of the Nile, was the capital and chief city of Makuria, and Faras, in the northern province of Maris, was a close second to Dongola in population and splendor. Soba, in the vicinity of modern Khartoum, was Alwa's metropolis. Dongola was located in the productive and relatively densely populated Letti Basin of the Nile Valley. The countryside of this fertile basin was dotted with numerous agricultural villages surrounded with well-tended fields, gardens, and pastures. The hinterland of Faras was not as productive as that of Dongola, but because it was an important military post, much of Makuria's revenue was lavished on this city. Little is known about Soba, but it has been suggested that it was at the end of a trade route whose other terminus was Lake Chad.

These cities were industrial as well as administrative centers. Pottery was intensively produced at both of these centers as well as at many other sites along the Nile. Especially abun-

dantly produced were the pots used in the wheels used to lift water for irrigation from the river. Other industries were iron smelting and textile weaving.

Part of the explanation for Nubia's medieval prosperity may be in the trade from Africa south of the Sahara to Egypt and the Muslim caliphate. Although little is known of this trade, treaty documents between Muslim Egypt and Makuria mention slaves to Egypt as well as wild animals (giraffes), ivory, and gold.

Alwa and Makuria's generally peaceable relations were not only a result of the familial relations of their royal groups; the two were somewhat isolated from each other because they were separated by more than 100 miles of a non-navigable reach of the Nile's great bend. Between Makuria and Muslim Egypt, a 600-year truce, though violated occasionally, usually prevailed after the peace treaty or Baqt, signed in 652.

West African Forest Polities

State formation in the southern forest regions of West Africa began by the end of the first millennium CE. Sources of political authority were largely based on religious and ritual power. The economic basis of small states and larger polities was almost always linked to food production, resource control, and specialist activities. Archaeology and oral traditions provide historians with a wealth of information about the rich artistic expression and world connections that characterized early polities.

When the archaeological site of Igbo Ukwu in the forests of southeastern Nigeria was dated to the end of the first millennium CE, many Eu-

ropean scholars were reluctant to accept the implications of its early beginnings. Since then the excavation of other forest sites has added to the picture of social and economic complexity that Igbo Ukwu provides. The intricately cast copper-alloy objects (850–880 CE) reveal a sophisticated technology and participation in a larger economic network. One object depicts a horse and rider, suggesting early trade connections between the forests east of the Niger River and North Africa. Moreover, the patterning of the figure's facial scarification was identical to ethnic markings of contemporary peoples, thus eliminating the possibility of their having been imported manufactures. One reconstruction of the ritual and high-status cache of artifacts interprets them in association with local traditions of titled elders, who ruled forest communities with advisory councils and ritual authority. Small forest polities such as this one likely persisted because of their appropriate scale and useful democratic underpinnings.

According to Yoruba oral traditions, Ife was the oldest state situated in the region of modern Nigeria, between the savanna, the northern woodlands of the Niger, and the forest of the coastland. The city of Ile-Ife marks the spot where the gods descended from the heavens to create the world and humankind. Olorun, the supreme sky deity, sent the founding ancestor Oduduwa to establish the state. Some traditions claim that his sons in turn founded the other 16 Yoruba kingdoms. Since this time, the ruler of Ife, the Oni, has claimed his right to govern based on the direct descent from Oduduwa, both ancestor and deity. It is also on this basis that the Oni in turn assesses the right of other Yoruba kings to wear the legitimizing beaded crowns of their royal privilege.

There is no doubt that Ife constitutes a likely site for early state development. Occupied since at least 350 BCE, Ife straddled the rich agricultural region of savanna and forest, marking a key gateway into the rich resources of the forest, including kola nuts, yams, and ivory, which would have been traded for metals, horses, and other goods. The early settlement was characterized by agriculture and iron- and bead-making technologies. Its access to predictable sources of high protein in the form of large forest snails and

SEATS OF POWER, SACRED SOURCES OF LEGITIMACY

In the early period (ca. 600–1100 CE) of Yoruba city-states, symbols of royal authority included large and elaborately carved stone stools. These objects are sacred artifacts and also historical statements about the sources of political authority. The origins of cities and states were located in the forest but at the same time were linked to key connections outside the forest.

An undated quartz stool (ca. 1000 CE) has a cylindrical seat and base connected by a curved elephant's trunk. The forest's largest animals, elephants, also provided valuable ivory for long-distance trade. The elephant image served as an eloquent and ancient symbol of leadership. A Yoruba proverb alludes to power as being like an elephant, the presence that cannot be ignored. A terra-cotta pot lid in the shape of an elephant head was excavated at Lafogido (ca. 1300 CE). It wears the beaded headdress and bead necklace associated with kingship. An earlier terra-cotta fragment shows a figure seated on a stool. Taken together, these works of art suggest the elevation and separation of the powerful elite. Divine kingship relied on both the forest and the spiritual and economic connections that extended beyond the forest realm.

Metaphorically, stools were the seats of power and in recent times reflect the elevated status of chiefs and kings. The elephant allusion in the quartz stool suggests the transference of power between the lord of the forest and the city-state. Such stools also played a role in rituals in which they served as "god's seat" and are found in sacred groves, where divine rulers and ordinary folks alike sought the sanction of ancestors and spirits.

—Candice Goucher

other game would have furthered the growth of population.

The rulers of Ife (and the city-states of Ijero, Owo, Ijebu, Ondo, Oyo, and others) were both male and female and situated their royal power with divine abilities and ritual roles undertaken on behalf of their communities. They too ruled with a council of male and female elders. Between about 500 and 800 CE, regional cities appear in the form of walled communities known as Enuwa,

a term for the original settlement meaning “we see eye to eye” and suggesting that early states came about through the mediation of conflict. The presence of monumental stone structures and complexes of buildings, streets, courtyards, and shrines define a style of urban architecture and planning at Ile-Ife and other forest sites in West Africa. An accomplished style of terra-cotta sculpture was also practiced. By the end of the first millennium CE, elaborately patterned potsherd and stone pavements (ceramic and stone tiles laid on edge in herringbone and basketweave shapes) with ritual pots set within or below and sophisticated copper-alloy casting also mark the flourishing of the distinctive city-state system that would spread over the next 500 years.

Similar constellations of large cities and emerging states on the forest edge are also situated in present-day Ghana and dated to between 1000 and 1500 CE, when local production and long-distance trade eventually characterized their growth. Among the 20 or more other potsherd pavement sites ranging from modern-day western Togo to Nigeria is the early city-state of Oyo (800–1200 CE). Stone beads were also an important item of royal trade from Oyo south along the Niger River to Benin, where they became the primary statement of political power in royal regalia, including crowns. The transformation of Oyo into kingdom and empire occurred much later, when trade and tributary systems extended all the way to the coast of Dahomey. Consistently present was an association of Oyo and subordinate kingdom political authority with Ife spirituality. Several historians have speculated that the basis for this continued religious influence was the practice of mediation by ritual specialists carried out at the center of Ife, long after its political power waned.

Political Change in East, Central, and Southern Africa

From 300 to 1000 CE Bantu-speaking peoples populated East, central, and southern Africa. They also successfully integrated, absorbed, or lived in union with the peoples who had already settled in these lands. In the fourth century CE most were organized into small matrilineal clans with a chief who could either be male or female or matrilineal clans led by a social and spiritual leader with little material authority. During this historical period some Bantu-speaking peoples were able to accumulate surplus by increased food production and, in some areas, better trading opportunities. As populations grew, some groups moved toward political centralization. Other Bantu-speaking peoples, especially those in less fertile regions, remained small populations with a political and social ideology of decentralization.

From 300 to 600 CE, southern Africa Bantu-speaking peoples mainly grew seed grains and raised cattle. They also formed small decentralized polities in which the matrilineal clan chiefs were primarily responsible for rituals such as the harvest celebrations and the redistribution of surplus food among the people. As cattle became the primary source of food, however, patrilineal ideology began to dominate. Some patrilineal clan chiefs were able to use their roles as distributors of cattle to create their own personal herds and thus attracted more followers.

The clans of chiefs with large numbers of cattle gained prestige. This in time led to the political concept of chiefly clans. North of the Limpopo in southern Zimbabwe the cattle-raising Shona began the centralization process, which would later result in the creation of centers of political power known as great and lesser Zimbabwe.

By 1000 CE Southwestern Africa began to experience different political consequences regarding the adoption of cattle. While the people began to integrate cattle into their food-production technologies, grain cultivation and gathering and hunting remained important sources of sustenance. Dual descent, rare in Africa, became the social order, and each person owed allegiance to both her or his father's and mother's clans. The

competing loyalties of dual descent tended to slow the centralization process.

Around 600 CE Bantu-speaking agriculturalists moved into East-Central Africa, organized into small matriclans, and continued to maintain a matrifocal philosophy of social organization. A possible reason for the continued decentralization could be that the soils in this region could not sustain a population through agricultural production only. Fishing was therefore often needed to supplement food production. The reliance on fishing and hunting encouraged the people of the region to work closely with the BaTwa, who were organized into nonhierarchical family bands.

North in the Upemba Depression of the Congo, the Luba-speaking peoples began to settle the region around the seventh century CE and came to control the rich resources of salt, iron, and copper found in the area. This helped to create a surplus, which led to social stratification. These peoples constructed irrigation systems and participated in long-distance trade. Although social stratification was developing, local village autonomy seemed to be the rule.

This period witnessed population growth in the Western Equatorial Forest based on banana production and the trade of iron goods. The BaTwa traded skins, honey, and ivory for Bantu-manufactured goods and agricultural foodstuffs. Even though the BaTwa traded with and lived in close proximity to the Bantu-speaking agricultural communities, they retained their loose decentralized forms of political organization. The surplus production and population pressures among the Bantu-speaking peoples, however, began to transform political organization, and lineage-based matriclans expanded. By 1000 CE these communities underwent a process of centralization, which led to the formation of larger kingdoms. These newer polities demanded and often received tribute from surrounding peoples. Bantu-speaking people of the Western Equatorial Forests transformed the concept of leadership by adding an additional meaning to their new word for leader, “to pronounce judgment,” which indicates that the new group of rulers enjoyed widespread judicial powers.

In the Mount Kilimanjaro region, the Chaga cultivators created elaborate trading networks

➤ AFRICAN DEMOCRATIC PROVERBS

A form of democracy was found in most of the Bantu-speaking societies in this region from 300 to 1000 CE. People were organized into matrilineal clans, and the person in charge was usually more a spiritual and social leader than a political one. A group of elders, both male and female, together with the leader made all the important decisions. To become an elder, one just had to have the luck to live long enough. During this era a chief was the one most able to provide peace and the ability to negotiate equitable settlement of grievances among peoples. Since leadership did not require warrior prowess, both men and women could become leaders. The following proverbs from the Bemba of Zambia symbolize this long-term attitude toward leadership:

“Ubukulu bwa chambeshi: Ukuicefya—The real leader, the big person is the one who makes herself/himself small.

Abantu lisabi: likonka maeshi aba no luse cikuuku, kabili ishiwi lisuma—Somebody must know how to speak kindness if she/he wants to build a village.”

—Christine Ahmed-Saidi

by harvesting crops in different kinds of environments. At the beginning of this period, the Bantu-speaking people in this area used the old Bantu word *mfumua* for “chief,” which was based on the older meaning of “the honored one.” By about 800 CE, however, they had created a new word for chief, *mangi*, that originally meant “the arranger, planner.” The difficult terrain of the Mount Kilimanjaro region led to the development of small independent chiefdoms. With the transition from *mfumua* to *mangi*, political power shifted away from individual clans to small territorial kingdoms. The *mangi* played the roles of mediators between the growing populations from these diverse clans. The *mangi*

also could use the age sets as communal labor in building and maintaining irrigation works, so in a sense they controlled public works. Under the mangi was the *njili*, which is a borrowed word from a Southern Cushitic language and was a type of clan headperson.

The Bantu-speaking Thagiicu, the Southern Cushitic Gumba, and the Nilotic Kalenjin lived in the Mount Kenya region. The Thagiicu adopted Southern Cushitic types of clan headmen who lacked a political role but wielded significant ritual responsibilities. Individual leaders were known as *mulamati*, which literally meant “the guardian.” A combination of the Kalenjin and the Bantu type age sets created a new form of cycling age grades in which every 40 years a new generation set would take over conduct of public affairs from the previous generation. This became a democratic nonchief-based society. Everyone could become an elder if they lived long enough.

As we have seen, this was a period of political change and consolidation in East, central,

and southern Africa. Although they would eventually change, the vast majority of East, central, and southern Africans would continue to reside in decentralized political polities for at least another 700 years.

■ Introduction: Eurasian States in Late Antiquity

In 300 CE, a band of large empires spanned Eurasia from the Atlantic to the Pacific oceans. Surrounding the African, European, and Asian shores of the Mediterranean was the Roman Empire. Occupying the Iranian plateau and reaching into central Asia, the Persian empire of the Sassanians interacted with the Roman empire to the west, the kingdoms of India to the southeast, and the China dynasties to the northeast.

China had once been united under the mighty Han dynasty, but that powerful and long-lived state had broken apart in savage civil wars, and the third century CE was disastrous for China. The Jin dynasty would briefly unite China, but in the first decade of the fourth century invading “barbarian” pastoral tribes from the northern steppe smashed through the Great Wall and occupied most of northern China. For the next three centuries, China would be divided. In southern China, refugees from the north established a

“pure Chinese” southern empire, which endured, ruled by five successive dynasties, for the next three centuries. In northern China, “barbarian” tribes from five different linguistic groups warred among themselves to establish supremacy. In the latter part of the fourth century, one “barbarian” group, the Toba, defeated the others and, as the Northern Wei dynasty, established a strong state that lasted for more than a century. By 534, the Northern Wei split into the Eastern and Western Wei, but by 581, the Sui dynasty crushed both of these states and in 589 conquered the Southern empire. The conquest of the south ended the long period of division. From that time to the present, China has normally been a united empire.

Like China, the Romans had experienced a disastrous third century. Civil wars and foreign invasions battered the empire, but by the end of the century Diocletian had reestablished order and stability. The Roman empire was to be, for

another three-quarters of a century, the strong and united arbiter of the Mediterranean world. During the fourth century CE, Constantine “the Great” moved the capital to Constantinople and set in motion the process that resulted in Christianity becoming the official religion of the Roman world, at nearly the same time that Mahayana Buddhism was becoming a major force in China.

This period of supremacy ended when Gothic invaders crushed the Roman Army in 379, signaling the beginning of the destruction of the empire. From then on, “barbarian” attacks on the northern frontier were relentless. By the early years of the fifth century, the western half of the Roman empire was occupied by Germanic kingdoms. The eastern half, centered on Constantinople, became the refuge for Roman civilization, similarly as the southern Chinese empire became the asylum for Chinese civilization.

Despite a brief revival of power in the sixth century when Justinian I sent Byzantine forces to recapture North Africa and Italy. The Byzantine empire, as modern historians know the eastern rump of the Roman empire, never regained more than a small fraction of the territory and might of its predecessor in its prime.

The great nemesis of the Byzantine empire was the Sassanian empire. The Sassanians had overthrown the Parthians in Persia in 224 CE and ruled Persia as a powerful Iranian and central Asian empire for four centuries, until the Muslims in 651 CE destroyed them. The Sassanian empire served as a commercial and cultural bridge between China/India and the Roman west and interposed an absolute blockade to any expansion of the Roman empire in Mesopotamia. The Sassanians located their capital not in Persia proper but rather in the rich agricultural Semitic-speaking Tigris-Euphrates Valley.

War between the Sassanians and the Romans, though intermittent, continued through this period until the fall of the Sassanians. The Roman-Persian conflict culminated in a war that lasted through the first quarter of the seventh century. The Sassanians were initially very successful, overrunning all of the Asian provinces of the Byzantine empire as well as Egypt and laying siege to the Byzantine capital, Constantinople. However, the Byzantine emperor Heraclius

turned the tide when his army of 50,000 defeated the Persians at the gates of the Sassanian capital, Ctesiphon. Heraclius’s victory in 627 CE brought peace and prostration to the two imperial antagonists, and it left both empires easy prey for the rising Muslim power that emerged from Arabia in 634. The Byzantine empire lost its wealthiest provinces to the Muslims, who simultaneously destroyed the Sassanian empire.

The Kushan empire, which had been a very prosperous state stretching from the Oxus River (Amu Darya) to the Tarim Basin (in modern Xingjian Province, China) and south to central India, lasted from the first century CE until it fragmented in the late third century. Its territories in India soon came to be ruled by the Gupta empire, which presided over Indian civilization during a golden age. The Gupta empire endured for three centuries (ca. 280–550 CE) and during that period led the world in scientific, mathematical, and much other cultural achievement. The empire of the Guptas weakened under the assaults of the “barbarian” Hephthalites (White Huns), who in the fifth and early sixth centuries emerged from central Asia to harass both the Sassanians and the Guptas.

These are only the most prominent of the Eurasian states in late antiquity. Others included the three kingdoms of Korea (Koguryo, Paekche, and Silla); the protostate of Yamato in Japan; Funan in Southeast Asia; the Pandyas, Cheras, and Chola of southern India; the Sri Lankan kingdom; and many more. During the three centuries of late antiquity, almost all of the smaller states adopted much of the high culture and civilization of their more powerful neighbors. Thus, the Korean kingdoms became Sinified, the nascent states in Southeast Asia were Indianized, and the new states in Europe and the Mediterranean world were Christianized. Regional civilizations were expanding by diffusing among the weaker civilizations surrounding them.

The Roman Empire in the Fourth Century

The fourth century was a period of fundamental transformation in the Roman empire. At the death of Diocletian in 305, it still retained its far-flung territories, stretching from Britain to the borders of Sassanian Persia. The emperors Diocletian and Constantine inaugurated new imperial systems, finances, and capitals. The adoption of Christianity as the state religion brought momentous change to the late ancient world. During the century, however, external invasions and internal rebellions challenged the empire as never before. In 395 the two sons of Theodosius I inherited what was to become a permanent division of the eastern and western empire, leading to two very different fates.

Controlling the unwieldy empire was a major problem. Imperial succession was rarely peaceful; sons of emperors, often still boys, needed the

support of the army to survive. Coemperors were often appointed for different territories. While this practice could expand control, it also multiplied the opportunities for rebellion. When Constantine divided the empire among his three sons, civil war broke out immediately, ending only when Constantine's nephew Julian had defeated all rivals. Military and attempted usurpations continued throughout the century, and the pressure to recruit troops exacerbated the entry of barbarian warriors into the empire.

Defense of the empire's long borders was the primary concern of fourth-century emperors, who often led campaigns directly. Intermittent war with Sassanian Persia continued until the seventh century and required a major commitment of Roman forces. Emperor Julian died on an expedition in Persian territory in 363, losing an important fortress. In the north, the Roman borders along the Danube and Rhine rivers were under constant threat by barbarian groups.

► CONSTANTINOPLE

In 330 Emperor Constantine inaugurated his new capital, Constantinople, on the site of the ancient Greek city of Byzantium. He chose a superb location at the intersection of Europe and Asia Minor, on the passage between the Mediterranean and the Black Sea, and at the intersection of two major military highways. At the heart of Constantine's city lay the Great Palace, the Hippodrome, site of imperial games and public ceremony, and the senate buildings. In the sixth century Emperor Justinian built the great church of Hagia Sophia nearby. A colonnaded avenue lined with columns and monuments led to one of the city gates and served as a route for imperial processions. In Constantine's time the city was one of several imperial capitals, but under his successors it became the permanent residence of the emperor and the central administration.

By the sixth century Constantinople was a huge urban center. The size of its population is debated, but it may have been as large as 500,000 before the Justinian Plague. Water was brought to the city in aqueducts and stored in huge cisterns, while grain to feed the population was brought from Egypt. The city was defended by a massive

The square in front of the Blue Mosque was once the site of the ancient Hippodrome in Byzantine Constantinople. Built between 203 and 330 CE, chariot races took place in the original Hippodrome, along with much of the civic life of early Constantinople. (Library of Congress)

system of land and sea walls and harbor defenses that protected it for centuries.

—Dorothy de F. Abrahamse

By 350 Alemanni and Frankish warriors were attacking important cities in Gaul. In 378 Emperor Valens and much of his army were killed at Adrianople in a disastrous battle against Visigothic immigrants, who were then allowed to settle in the Balkans as federated warriors.

Fourth-century emperors also made important innovations in government. They created a new senatorial class dependent on the emperor and restructured the organization of the army and provincial government. An expanded bureaucracy was responsible for collecting the revenues needed to support the empire, and controls were placed on the mobility of city dwellers and farmers. The emperors themselves were seen as Christ's earthly representatives, appearing in person or through their statues in glittering ceremonies.

The Fall of the West Roman Empire and the Emergence of Successor States

The parallels between the two great Eurasian empires in the Classical Age, the Han dynasty and the Roman empire, are striking, although parallel events were not always simultaneous. Both empires had, for long periods, established peace and prosperity over large parts of the Eurasian world. But both empires, after their centuries of glory, collapsed or were destroyed. Similar causes operated in both cases: impoverishment of once-free peasantries, increasing militarization of society, crushing taxation, and alienation of the people from the state.

The precipitating cause of the collapse of the West Roman empire was the invasion by Germanic tribes in the early fifth century. With the frontier defenses weakened, large groups of German tribesmen moved across the frozen

Rhine in the winter of 405. They weakened and slowly took over the Roman political structure and had a similar impact on towns and rural areas. The cities, particularly north of the Pyrenees and the Alps, retreated behind walls on an average of half their original size, while in the countryside Germans took over the land and three-quarters of its revenues. The Roman army withdrew from Britain, which was then overrun by Angles and Saxons. North Africa fell to the Vandals, while the Franks became supreme in Gaul. In all parts of the west Roman empire, the invaders and those they invaded were transformed by this experience.

Among the first states to emerge from this transformation process were those of the Visigoths in southern Gaul and the Ostrogoths in Italy. Pressure from the westward-moving Huns drove the Visigoths into Roman territory around 376. Having defeated the eastern Roman army (Adrianople, 378), the Visigoths wandered within the empire for 40 years, eventually sacking Rome under Alaric (410) before settling in Aquitaine (417/418).

The Roman emperor of the West, Constantius III, assigned the Visigoths in Gaul to the defense of Roman territory against local unrest and other Germanic groups. Benefiting from relative peace, the Visigoths expanded in southern France and northern Spain and slowly established the kingdom of Toulouse. But expansion came to a halt under Alaric II (484–507), who emphasized fusion of Romans and Goths, published an important code of law (*Breviary of Alaric*), and convoked the first national council of the church under Germanic leadership at Agde (September 506). The kingdom of Toulouse disappeared when defeated by Clovis and the Franks (507), after which the Visigoths retreated to Spain, where they flourished until the Arab conquest of the eighth century.

In 488 the Ostrogoths were sent by the Eastern emperor to Italy against Odoacer (476–493). This invasion contributed to unifying the Ostrogoths and led to the establishment of the second Gothic successor state in the West. The Ostrogoths built a network of alliances with friendly tribal groups around Italy, acted as the official legitimate imperial army in the West, and used Roman senators in their administration

THE FALL OF ROME—DESTRUCTION OR TRANSFORMATION?

Ever since Edward Gibbon published *The Decline and Fall of the Roman Empire* (1776), the question of the fall of Rome has been hotly debated. Gibbon mainly blamed Christianity and the Barbarians for the decline of the empire in the West, whereas recent scholarship has presented multi-causal explanations to emphasize transformation instead of immediate collapse.

Recent scholarship based on theories of ethnogenesis has emphasized that the formation of distinct identities among Germanic peoples occurred only after their incursion within Roman territory. Continuity with older Germanic groups was minimal and was mostly used for propaganda purposes by leaders of both groups. Germanic kings of newly risen states in erstwhile Roman territory claimed to be ruling under Roman auspices and attempted to act as Roman officials. The outstanding example of this was Theodoric, ruler of Ostrogothic Italy. Theodoric was generally acclaimed as a wise and tolerant ruler, which earned him the title of “Great.” His reign is especially known for his renewal of social and cultural aspects of traditional Roman life, as the monuments of Ravenna still show prominently. Despite Boethius’s execution, there is no evidence for general hostility from the Roman aristocracy. Even ecclesiastical writers praise his neutral involvement to settle matters of the Church. The destruction in Italy wrought by the Byzantine reconquest in the sixth century was, by all accounts, much worse than the Gothic occupation of the fifth century.

From East Rome to Byzantium, 395–641 CE

Between the fifth and seventh centuries, Byzantine civilization emerged from the Roman empire. Its centralized imperial system survived barbarian threats and internal unrest and was able to mobilize resources of manpower and wealth. As Christian theological controversies

THEODORA, JUSTINIAN'S PARTNER IN EMPIRE

Although women, such as Empress Irene, did sometimes rule the Byzantine empire on their own, this was unusual. But as wives, mothers, and sisters of emperors they were often powerful political figures. The Empress Theodora (ca. 500–548) was one of the most colorful and influential women in the early Byzantine empire. Historians must interpret her life from a slanderous diatribe (the *Secret History* by Procopius) that is the main source for Theodora. We do know that Theodora came from a disreputable background. She was an actress, a hereditary profession that was considered similar to prostitution. In order to marry her, Justinian had to issue a law allowing penitent actresses to marry with imperial permission.

Theodora was a strong partner for Justinian. As empress, she closed brothels, founded a convent for repentant prostitutes, and helped the destitute. She also intervened on behalf of women who were political victims. Theodora was a Monophysite, and with Justinian's permission she sheltered monks and clergy of this belief. Her influence was important in a popular rebellion known as the Nika Revolt. In 532 the popular factions in the Hippodrome joined in riots against Justinian's officials and burned much of the city. According to our sources, Justinian lost his nerve and considered flight, but Theodora persuaded him to stay and put down the rebellion. Until her death in 548, Theodora played an important role in Justinian's decisions. Her regal presence is vividly evident in a mosaic in San Vitale, Ravenna, where she stands opposite her husband Justinian in the nave of the church.

bitterly divided the east, Byzantine emperors took on the role of protectors of right belief (Orthodoxy). Greek became the language of law and administration, and rulers began to use the Hellenistic term *basileus* (king). They ruled a civilization still interconnected around the eastern Mediterranean. The eastern empire remained a world of thriving cities, large and small, that produced trade, wealth, and frequently popular discontent in the fifth and sixth centuries. The emperor Justinian was able to marshal the resources of the empire to recover territory and mount a massive building cam-

paign in the sixth century, but new invasions from Persia and Arabs almost destroyed his successors. Historians now characterize the period between the fourth and seventh centuries not as a period of decline but as a distinctive and vibrant society known as late antiquity.

Fifth-century rulers of the east faced many of the same barbarian threats as their western counterparts. Pressured by the Huns, the Visigoths and later the Ostrogoths crossed the Danube frontier into the Balkans, and their generals threatened the empire. Eastern rulers, however, were able to offer subsidies to the

invaders and recruit armies from within the empire to oppose them. They were also helped by geography, as the Visigoths and Ostrogoths moved west into Spain and Italy, while the Persian border remained peaceful. Religious controversy was at its height in the fifth century, as great Church councils debated the definition of the human and divine natures of Christ. These arguments were not just abstract; they reflected deep divisions in belief between areas such as Egypt and Syria with Constantinople and the west.

The emperor Justinian (527–565) was one of the most important Byzantine rulers. His acts addressed every aspect of his society, beginning with a codification of imperial law that became the basis of Roman law for Europe in later centuries. He issued theological edicts, held a Church council, and attempted to restore religious unity. Justinian carried out a massive building program that created churches and fortresses throughout the empire. Most important was the huge domed church of Hagia Sophia (Holy Wisdom) that became the center of imperial religious ceremony. To restore the western empire, Justinian sent out campaigns that began with the reconquest of Africa from the Vandals in 533 and moved on to Italy. The reconquest of Italy from its Gothic rulers was long and difficult and was interrupted by renewed wars with Persia and the outbreak of the plague. Even in his own age Justinian's program was controversial, and many modern historians argue that its expense fatally weakened the empire.

Justinian's successors faced crises almost immediately. New migrations increased pressure on the expanded borders, as a central Asian group known as the Avars moved west. Italy remained Byzantine for only a few years before Lombard invaders, fleeing the Avars, took most of Justinian's conquests. The Danube frontiers came under new threat from the Avars and the Slavs. The Slavs, who lived in small groups, began to settle in the Balkan Mountains and raid as far south as Greece during this period. The crisis came to a head in 602 when a rebellion against the emperor Maurice led to civil war and gave the Persian armies a reason to invade. By 613 they had entered Jerusalem, where they took the Byzantine relics of the True Cross and moved on to conquer Egypt and invade Asia Minor. The

Persian rulers seemed ready to annihilate their old rival Byzantium.

But the new Byzantine emperor Heraclius led a remarkable comeback. He organized a new army and trained it in Asia Minor, remaining on the frontier even when Constantinople endured its first great siege by the Avars and Persians. The siege demonstrated the great strength of Constantinople, as the invaders were unable to breach its walls, and the use of Greek fire decimated their boats. Eventually Heraclius was able to regain the lost Byzantine territory along with the True Cross and to restore it to Jerusalem in a ceremonial triumph in 630. But the two empires had drained their resources in the wars. The cities and countryside of both empires were gravely damaged, and archaeology shows that many cities and villages were abandoned in the seventh century.

Neither was prepared to resist an unexpected new enemy from the desert, as the Arab followers of Muhammad began to attack the cities of Palestine in 633–634. They fell quickly and decisively, and by the time Heraclius died in 641, Palestine, Syria, and Egypt were lost to the Byzantine empire.

The Sassanian Empire

The Sassanian empire was the third of the great Persian empires in Classical and late antiquity. The first was the Archaemenid empire that was founded by Cyrus the Great about 540 BCE and lasted until its conquest by the Macedonian Alexander the Great in 333 BCE. Alexander's Greek successors ruled much of Persia until the rise of the Parthian kingdom in 250 BCE. The

Parthian kingdom, also known as the Arsacid empire, by the first century BCE, expanded to include Mesopotamia as well as most of Iran.

The Arsacid empire thrived nearly half a millennium until supplanted by the Sassanians in 224 CE. Tradition traces the dynasty to Sassan, a third-century CE Persian who was a shepherd and Persian Holy Man. His grandson, Ardashir I, at first was a vassal of the Parthians. As king of Fars in southern Iran, he is said to have claimed descent from the great rulers of the Archaemenid empire. Rebelling against Arsacid overlordship, Ardashir killed Artabanus V, the last Parthian king, and established the Sassanian (Sasanid) empire. By 226, he seized the luxurious Arsacid capital of Ctesiphon and assumed the title of shahinshah (king of kings), which had been the ruling title of the Archaemenid emperors. Ardashir also established Zoroastrianism as the state-sponsored religion.

The Sassanian empire endured for more than four centuries and, like its Persian predecessors, took its place as one of the great powers of the Eastern Hemisphere. At its greatest extent under Shahinshah Khosrau II (r. 591–628) the Sassanian empire stretched from west of the Egyptian Nile to the Indus River and ruled an area from the Mediterranean Sea and the Caucasus to central Asia and the outer limits of the Chinese empire and had client states in Oman and Yemen. Even in its more modest usual boundaries, it spanned the territory from Syria and the Caucasus to modern Uzbekistan and central Afghanistan. The mighty Roman empire fought numerous wars with the Sassanians and sometimes paid tributes to the Sassanians amounting to thousands of pounds of gold for peace.

On their western frontier, the Sassanians fought and traded with the Romans. The eastern cities of the Sassanian empire did the same with the oasis cities on the Silk Roads, and in the southeast the empire conducted intimate commercial and cultural relations with the kingdoms of India, including the Gupta empire. But the Sassanian empire was not only a commercial and cultural bridge between the East and West; it also was the location of a vigorous economic and cultural achievement on its own merits, to which the Sassanian university and the medical institute of Gondeshapur testify.

➤ IMPACT OF TOLERANCE IN EMPIRES

How states deal with diversity is important. Some tolerate just about anything that does not threaten their existence. Others insist on homogeneity and conformation. This varies over time. Most societies alternate between tolerance and conformation. Neither is a guarantee for success. The Persian empires survived for more than 1,000 years, from the sixth century BCE to the seventh century CE, with some interruptions. Their experience is interesting. The Achaemenids tolerated a wide variety of peoples and religions. They are remembered for allowing the Jewish Babylonian exiles to return and build a new temple in Jerusalem. Other peoples in the empire were treated with tolerance. This included many Greeks, who often performed well in imperial armies. Alexander continued this tradition, as did most of his Hellenic successors. There were exceptions such as that presented by the Seleucids (305–ca. 90 BCE) under Antiochus, leading to revolts such as that of the Maccabees in the second century BCE. The Parthians modeled their rule on that of the Achaemenids and sponsored widespread tolerance of diversity, often capitalizing on this in their conflict with Rome. The Sassanians did not follow this tradition. Their sponsorship of orthodox Zoroastrianism often led to persecution of dissenters in their empire. That did not, however, prevent their exploiting the discontent of dissidents, both Christian and Jewish, in the Byzantine Empire. It also did not result in such severe persecution of Persian Jews that it prevented completion of the Talmud by scholars in Mesopotamia, still the primary source of Orthodox Jewish law. Their departure from the greater tolerance of the Parthians did lead to many subject peoples welcoming the Arab Muslim conquerors. This paralleled the response of Byzantine subjects to the Arab Conquest. It seems that while tolerance does not ensure survival, intolerance provides fertile ground for subversion.

—Daniel E. Spector

Sassanian government combined a patrimonial, almost feudal, system of local government with some degree of centralization. Hereditary magnates (*shabrdars*) governed many of the provinces. With the higher Zoroastrian clergy, these magnates constituted a powerful governing class without whom only a few rulers found

it possible to govern. These magnates controlled vast territories and enjoyed princely incomes. Next in prestige were the lower clergy and bureaucrats and then the class of warriors known as *artestdar*. These warriors served as heavily armored cavalry, or *cataphracts* or *clibanarii*. They were the knights of Sassanian Iran and the antecedents of medieval European knights. The *artestdar* were a very haughty lot, proud of their genealogy and disdainful of the impoverished commoners. These warriors were given hereditary estates so that they would be able to afford

the armor, the weapons, and the special horses that their military service required.

The commoners were artisans or peasants, often living as hereditary serfs. They were exploited and occasionally engaged in widespread peasant uprisings, which the *artestdar* and the government suppressed with a measure of brutality. The most serious of these peasant uprisings was that of the Mazdakists, which occurred at the end of the fifth and beginning of the sixth centuries. The Mazdakists were the followers of Mazdak, a charismatic holy man who preached, if the reports of his enemies are to be believed, the sharing of the landlords' and the Zoroastrian churches' wealth and women. Initially, the reigning shahinshah, Kavadh I, favored the Mazdakists, but the Zoroastrian clergy and the majority of the nobles overthrew him. When Kavadh regained power in the early sixth century, he allowed a pitiless proscription of the Mazdakists, massacring thousands.

Although there was much religious diversity in the Sassanian empire, with many Jews, Christians, and Buddhists, the majority and official religion was Zoroastrianism. Jews and Buddhists usually received broad toleration, but toleration of Christians alternated with persecution, often shifting with the imperial succession. Although both Manichaeism and Mazdakism received initial favor by the reigning shahinshah, both were regarded by the Zoroastrian clergy as Zoroastrian heresies and were suppressed.

The Zoroastrian clergy, like the medieval European Christian clergy, were extremely potent. They controlled much of the wealth in the empire and wielded great political power. Religious orthodoxy became a state goal. This was similar to what happened in the Roman empire after Christianity became the state religion in the fourth century, intolerant of non-Christians and Christian beliefs that deviated from orthodoxy. Both empires tried to subvert religious minorities in each other's domain, and this became a theme in the imperial conflict. When Persian armies took Jerusalem in 614, the Jews there welcomed the change; dissident Christians elsewhere in the Byzantine empire often welcomed their Persian conquerors as more tolerant than their Christian leaders. This foreshadowed what would soon happen when the Arab Muslims conquered territories

in both empires. They were often welcomed as relief from persecution by orthodox religious elites.

The third and fourth centuries and the sixth century were periods of grandeur for the Sassanian empire, but during the fifth century the imperial fortunes sank to a low point. In the second half of the fifth century, a prolonged famine swept the land (464–471), peasant distress was rife, civil conflicts abounded, the Mazdak insurgency occurred, and the Hephthalites, a pastoral people from central Asia, forced the Sassanians to pay tribute. Immediately after the famine, the Hephthalites attacked Herat in the eastern part of the empire. The shahinshah, Perooz I (r. 457–484), after some initial victories was captured by the Hephthalites and held for ransom. Perooz agreed to pay tribute to the Hephthalites and even surrendered his heir, Kavadh, to them as a hostage. Then, the Hephthalites intervened on behalf of Perooz in a civil war. On Perooz's death in 488, Kavadh ascended the throne and fell afoul of the Zoroastrian clergy for supporting the Mazdakite insurrection. Although the clergy allied with the nobility deposed Kavadh, he sought refuge among the Hephthalites and married the daughter of their king. The Hephthalites again intervened in Persian civil strife, assisting Kavadh in recapturing his throne. Kavadh and his Hephthalite allies then attacked the Romans in the west and won several victories. But the Hephthalites proved to be fickle allies and continued to raid Sassanian territory until finally defeated by Shahinshah Khosrau I in 557.

Historians have called several Sassanian rulers “the Great.” Shapur I the Great (r. 240–272) is remembered as a great warrior who defeated the Romans and as a builder of cities including Gondeshapur, later the location of the famous university. He built roads and dams that stimulated agriculture and the economy.

Shapur II (r. 309–379) is also called “the Great.” The nobility crowned him while still in the womb; the crown was placed on his mother's belly. He fought many wars against the Romans although without great results. His conquests included Armenia, the area now known as Afghanistan, and part of Pakistan, where he subdued and annexed the Kushan empire.

Perhaps the most renowned Sassanian ruler in Persian legend is Braham V (r. 421–438). A

great warrior, he repeatedly defeated the Romans and dealt the Hephthalites a severe defeat near Bukhara, in modern Uzbekistan. A model Persian gentleman, he was immortalized by the Muslim Persian historian Firdausi in his epic *Shahnameh (Book of Kings)* (ca. 1000 CE).

The end of the Sassanian empire came in 642, when the last shahinshah, Yazdgerd III, was defeated (some say killed) by the Muslim Arabs. Although the Tang dynasty maintained his successor, Perooz II, and a court in exile for several decades, the Sassanian empire was only a memory.

The Guptas in India

The Gupta rulers gave northern India its so called classical age, that era when a society accepts its political and social structures and develops refined standards for its artistic and literary culture. The reign of these “imperial” Guptas, 319–467 CE, also saw the integration of ancient beliefs, local customs, and bardic legends into the conglomerate yet classical pattern of Indian culture and the equally conglomerate religion that foreigners would later call Hinduism. The Gupta empire was neither the largest nor the mightiest in India's long history, but it was the one that supported and sponsored this classical culture.

➤ FAXIEN: A RELIABLE WITNESS?

Historians seeking accurate accounts of past events usually look for primary sources (i.e., documents or eyewitness accounts, perhaps in memoirs or letters) describing such events. These are usually, but not always, considered more reliable than secondary or more remote transmissions.

For India's Gupta empire, the primary evidence is fragmentary: coins, inscriptions on pillars, rocks, and copper plates. However, there is one eyewitness account, that of a Chinese monk named Faxian. Faxian resided in Gupta India from 401 to 411 CE, after which he took a ship to Singhala (Sri Lanka), where he spent two years before moving on to Java. He had plenty of opportunity to observe the Gupta state and the life of the people within it.

However, Faxian's interest was focused on Buddhism. He seems to have spent most of his time studying Buddhist manuscripts, visiting holy places, and hearing tales of events in the lives of the Buddha and his principal apostles. Only two passages mention rather casually the lives of the people, and these give such sugarcoated views

that they must be questioned. One says that there were no capital punishments, merely fines for crimes, and no butcher shops or dealers in intoxicating drinks and that the only meat eaters were the low-caste Chandellas. In the other passage, he says that the townspeople "vie with one another in the practice of benevolence and righteousness" and that wealthy families set up dispensaries to provide medical care for all the poor.

There is enough evidence in the law codes and the literature of the day to assert that Faxian was not aware of what was happening around him. Or perhaps he was aware but felt that as a guest he should not tell unpleasant facts about his hosts.

—Edwin Hirschmann

A Record of Buddhistic Kingdoms, Being an Account by the Chinese Monk Fa-Hien of His Travels in India and Ceylon (A.D. 399–414) in Search of the Buddhist Books of Discipline, translated and annotated by James Legge (1865; reprint, New York: Paragon, 1965).

This empire, which came to rule much of northern, eastern, and central India, had as its core area Magadha (southern Bihar) and as its capital Pataliputra, as had the mighty Maurya empire roughly 500 years earlier. It reached for empire when its heir, Chandra Gupta I, married a princess of the powerful Lichchavi tribe of northern Bihar, absorbed their lands, and began adopting imperial titles and trappings. (This Chandra Gupta must not be confused with Chandragupta Maurya, founder of that dynastic empire. Perhaps the former tried to emulate the latter, but there was no family connection.)

Samudra Gupta, 335–375 CE, followed his father's lead by sending the armies to conquer the upper Gangetic plains and, if inscriptions are reliable, then south, along the Bay of Bengal coast, to the area of present-day Chennai (Madras). Samudra Gupta is said to have subdued many "kings," although he restored some to their administrative roles as his tributaries. Annexing conquered lands and ruling through imperial officials was not the usual practice of those times.

Samudra Gupta, in addition to his political and military skills, was portrayed as an accomplished poet and musician.

The Gupta empire peaked with the reign of Chandra Gupta II, 375–415 CE, sometimes called "Vikramaditya." His army carried the reach of empire westward beyond the Indus Valley, wiping out what remained of Kushan and Shaka "satraps" or feudatory chiefs. Like his father, he claimed to be a "universal" emperor, and his conquests are listed on a commemorative iron pillar, now in Delhi.

Such inscriptions, on pillars, copper plates, caves, and walls, must be used by historians, along with dated coins, to understand the history of classical India. It is a jigsaw puzzle with many pieces missing. There are few narratives or chronicles. Literature of the time gives us some materials, but they are not historical records; even learned treatises on state and society are prescriptive (telling how life should be) rather than descriptive (telling how it actually was). Thus, we have *shastras* on the law and state as-

cribed to Manu, the legendary lawgiver, and later sages but no records of actual trials or administrative proceedings. Some historical insights can be gleaned from the *Arthashastra* of Kautilya, which is too subtle and sophisticated to have been imagined. For instance, Kautilya urged frequent checks against fraud by state officials, since such theft is as hard to detect “as it is to discover when the fish drinks water.” The historical Kautilya was the minister to Chandragupta Maurya, but the language of the *Arthashastra* indicates that it was written during Gupta times.

In classical India the monarch was divinely anointed through ceremonies by leading Brahmins (much as in medieval Europe). Kingless states, called “republics” or “oligarchies,” were gradually eliminated from most of India. The reigning monarch chose his successor, and the successor was not always the oldest son. This led to some gory episodes: Chandra Gupta II reputedly became king by killing his brother. Despite their divine sanction, kings did not rule absolutely. They were a part of the socio-religious system called *dharma*, divine law or duty, and the king who violated *dharma* by turning tyrant forfeited his subjects’ loyalty. The wise king valued public opinion and, of course, Brahmanical opinion.

Rulers and warriors supposedly came from the *varna* (caste) of the Kshatriyas, but most of the ministers seem to have been Brahmins, and members of other *varnas* could occasionally rise to high position through their merits and the fortunes of politics. Generally, though, the low-castes and no-castes were supposed to do the dirty work and serve their “betters.”

The king ruled through his administrative machinery, for, as Kautilya wrote, “a single wheel cannot move by itself.” He chose senior advisers, called *mantrins*, who met in council. Members included the *purohita* (court priest), the *senapati* (army commander), the foreign minister, the chief judge, and other functionaries. There were also the *amatyas*, administrative assistants to the king. One pillar from Gupta times refers to a *sabha*, apparently a popular assembly, but tells nothing of its selection or its role in the state. The Guptas also had an established system of provincial and local administration, with royal governors running the directly

ruled provinces. Those provinces were divided into districts, administered by district officers assisted by appointed councils. Towns and villages also had councils of prominent local citizens to attend to civic business.

Areas that retained their autonomy had kings who acknowledged the sovereignty of the Gupta ruler and sent him gifts and tax revenues, in return for which they were confirmed and protected on their thrones. Should the central power weaken, these regional feudatories might assume larger measures of independence and authority. This was most likely in frontier areas where access was difficult and in minor states that had been swallowed whole by the empire. When Chandra Gupta II married the princess of the Vakatakas, rulers of a substantial central Indian kingdom, he brought that state into the empire.

Despite India’s philosophies of nonviolence, warfare and aggressive diplomacy seem to have been normal interstate behavior. Kautilya wrote that a ruler should consider all bordering neighbors as his natural enemies and seek to weaken or upset them. But if one’s neighbor is a natural enemy, the state on his far side would be a natural ally with whom one could work to destroy their mutual foe. Kautilya built up a system of situational chesslike gambits known as the *mandala* theory, advising a ruler how to weaken his enemies and strengthen his own position. A proper army, according to classical doctrine, included infantry, cavalry, chariots, and an elephant corps, although by Gupta times the chariot was fading into military insignificance. Though wars were frequent, we have no historical accounts of invasions and battles or destruction and casualties, making them seem abstract and bloodless.

Law in classical India was not considered a product of legislation or royal decree but instead was a fulfillment of *dharma*, divinely dictated and merely elaborated by earthly authorities. Law codes of Gupta times show a greater preoccupation with property rights than had earlier renditions, indicating a society settling down with increasing contentions over land occupancy. Trial judges could consider existing customs and changing conditions as well as the codified laws, but again we have legal prescriptions attributed to brilliant scholars rather than descriptions of actual ordinances and trials.

The Gupta monarchs do not seem to have participated directly in economic activities, perhaps because of the vigorous and well-organized mercantile and banking establishments. As seen, the rulers provided an effective court system that respected property rights, and they made a fine art of minting silver and gold coins. To help commerce they maintained and policed highways. To help agriculture they built dams and irrigation systems, since the prudent use of river and rain waters was already becoming a subject of general concern. There was talk of state regulation of market prices and banking rates, but whether anything effective was done is not known.

The principal source of state finance was the land revenue, in Gupta times and after, until the modern Indian Republic. It was usually set at one-sixth of the farmer's harvest, though it might rise as high as one-third. It is called simply "land revenue" to avoid the knotty problem of whether it was taxes or rent, whether the monarch "owned" all the land in the kingdom. "All land belongs to the king" was a truism often heard but not meant in the Western sense. He could not simply seize it and oust the peasant without justification. If he did so he could be accused of violating dharma, and if he did it too often he might find himself without a kingdom. Except for those on explicitly temporary lease, the peasants had a recognized right of occupancy if not ownership.

The most distinguishing role of the Gupta court was as the generous patron of learning and literature in classical Sanskrit. Ancient Sanskrit had been retained for sacramental use in Vedic prayers, though it had dropped out of everyday speech. Now it was revived with elegant complexities as the language of India's learned and cultured elites. The court of Chandra Gupta II hosted "The Nine Jewels," accomplished Sanskrit poets and writers. Among them, it is generally believed, was Kalidasa, brilliant poet and dramatist whose romantic drama "Shakuntala" introduced an idyllic legendary India to the West. Science also flourished in Gupta times, with Aryabhatta the most renowned astronomer and mathematician whom some feel first invented the decimal system.

The Gupta empire peaked with Chandra Gupta II in 415 CE, but empire and dynasty con-

tinued. His son and successor, Kumara Gupta, maintained the empire for 40 years. When insurgents threatened, Kumara Gupta's son Skanda Gupta crushed them and then succeeded his father in 454 CE. However, the empire was soon threatened by a serious invasion from central Asia by the Huns (called Hunas in India), cousins of those invading Europe at about the same time. As in Europe, they were depicted (by their victims) as brutes and monsters of depravity. Skanda Gupta repelled the Hunas in a fierce battle, but some imperial feudatories used the distraction to gain power or even break away from the empire.

With the death of Skanda Gupta in approximately 467 CE, the line of succession becomes murky. A brother, Puru Gupta, apparently succeeded, followed shortly by two of Puru Gupta's sons. Then Budha Gupta, a son of Skanda Gupta, ruled from 477 to about 500 CE. But the Hunas then returned in force, and the emaciated empire succumbed to their attacks. Under the terrifying Toramana and his son, Mihirakula, the Hunas raided and ravaged northern India. This ended around 530 CE when a Gupta feudatory, Yashodharman, seized control, rallied the home forces, and drove the Hunas into Kashmir. After a decade of personal power, Yashodharman disappeared. Gupta heirs resumed their throne in their Magadhan heartland, but the empire had been shattered.

Christian Africa in Late Antiquity

From the early fourth century to the late seventh century, North Africa was a Christian land. Christianity in North Africa enjoyed its golden era in the fourth century. The Catechetical School of

Alexandria produced great scholars such as Tertullian and Cyprian.

The Egyptian or Coptic Churches spread the Christian faith in the local (Coptic) language, and many churches emerged in the interior of Egypt. The Roman government's fitful campaign to suppress Christianity reached its peak when Emperor Diocletian launched a major attack against Christians during 303–305, but this suppression came to an end in the year 312 when a pro-Christian emperor, Constantine, issued a decree of religious freedom.

In the fourth century, the era of monasticism commenced. This movement started when devout Christians left families and cities in order to live ascetic lives as hermits in the desert. Antony (251–356), a hermit from Egypt, is often referred to as “the African Father of Egyptian Monasticism,” while Pachomius (ca. 287–347) founded Coptic monasteries that were ruled by poverty and obedience. Augustine (354–430), the bishop of Hippo, also founded monasteries in North Africa, and his monastic rule had great influence in the universal Church. In spite of its triumph in becoming the orthodox religion of the Roman state, Christianity in North Africa experienced doctrinal conflicts that led to internal divisions. In these conflicts, African bishops such as Athanasius and Augustine were in the vanguard of defining the accepted orthodox position.

Donatism, a doctrine propounded by Bishop Donatus of Carthage, denied Church members who had collaborated with Christian persecutors admission back into the Church. Augustine argued that the Christian message did not depend on the moral character of the messenger but instead depended upon God, the giver of salvation. Later on, Augustine accepted the collaboration of the imperial authorities in fighting the Donatists. The imperial authorities resorted to armed violence to suppress the Donatists. However, the Donatist schism continued to prevail in North Africa until the invasion of the region by Islam in the seventh century.

The Christian church in Egypt, led by the archbishops of Alexandria, refused to subscribe to Christian orthodoxy as defined by the archbishops of Constantinople, who were supported by the Byzantine emperors. In their conflict with the Byzantine archbishops and emperors,

the Egyptians embraced Monophysitism, a complex and unique understanding of the nature of Christ. This doctrinal dispute with the Byzantine authorities strengthened the Egyptians in their nationalistic defiance of imperial authority. The indigenous Christian church of Egypt came to be known as the Coptic Church (after Copt, a Greek word for the native Egyptians).

The split within the Orthodox Church became wide and bitter. After the fifth century, imperial authorities maintained a Greek archbishop in Alexandria in rivalry with the indigenous Coptic archbishop. During the wars between the Byzantines and the Persians, the Copts sided with the Zoroastrian Persians rather than the Christian Byzantines. When the Muslims drove the Byzantines from Egypt in the 640s, the native Egyptians stood on the sidelines and cheered. Invasions by Vandals in North Africa marked the beginning of the decline of the Church in North Africa. The Vandals had been converted to Arian Christianity in the fifth century and were hostile both to Donatists and Catholic Christians. In 533, Byzantine invasions led by Justinian defeated the Vandals. Justinian tried to revive Catholicism by expelling Donatists and Arians from the churches, but the prosperity of the third and fourth centuries was never fully restored. However, it was during the reign of Justinian that Christianity spread to Nubia, the Sudan, and Ethiopia. Some evidence indicates that Christianity had already been in Ethiopia as early as 350 in Aksum. Regardless of the great attention he gave to the struggle between the orthodox and the Monophysites, Justinian failed to bring about religious unity in his empire. His conquest of Vandals did very little to stop the decline of Christianity in North Africa.

The coming of Islam to North Africa in 639 further weakened the divided Christian communities of this region and displaced Christianity on a large scale. In 667, Arab armies invaded the province of North Africa and built the city of Kairowan as its religious and military center in North Africa. By 709, the whole of North Africa was in the hands of Arabs. Unconverted Christians were allowed to practice their religion if they paid a tax and renounced proselytizing for Christianity. There was a significant increase in Islamic converts. Within a century, the Christian

Church in North Africa, except for the Nubian kingdoms, had died out without any direct persecution. The Nubian kingdoms of Nobadia and Makuria that united under the name of Makuria's capital, Dongola, managed to fight back Arab forces and flourished as a kingdom until 1317, when the Dongola Cathedral became a mosque.

Chinese States during the Period of Disunity, 184–589 CE

The Period of Disunity in China lasted more than three and a half centuries, from the fall of the Han dynasty until the rise of the Sui dynasty. It is often dated as starting with the deposition of the last emperor of the Han dynasty in 220, but many Chinese historians (as well as the authors of *The Romance of the Three Kingdoms*) prefer to date it from the Yellow Turban Rebellion, which began in 184 and spelled the de facto end of Han dynasty power.

The Yellow Turbans were a Daoist sect in Shandong that led a peasant rebellion against extortionate taxation and bureaucratic oppression. Although the leader of the Yellow Turbans was killed, his rebellion spread, eventually engulfing most of northern China as well as Sichuan and requiring the mobilization of vast armies for its defeat. These armies managed to suppress the uprisings but only at the cost of massive death and destruction and the effective loss of imperial unity. The commanders of the regional armies rose to become warlords of their devastated areas, and the nominal emperor became a puppet of one of the leading generals, Cao Cao (from whom the dish General Tsao Tsao's

chicken, common in American Chinese restaurants, takes its name).

After years of warfare among the warlords, three kingdoms emerged.

In the north, centered on the Han capital of Loyang, General Cao Cao ruled through a puppet Han emperor, but in 220 Cao Cao's son deposed the puppet and established the Wei dynasty. Shortly after, another warlord proclaimed the Shu Han dynasty in Sichuan, while the Yangzi Valley and the south became the home of the Wu dynasty. These three kingdoms were at nearly incessant war from 222 to 265, warfare that is the major theme of *The Romance of the Three Kingdoms*, one of China's Four Great Novels. *The Romance of the Three Kingdoms* was written in the thirteenth century.

All the three kingdoms confronted similar problems, the most pressing of which was to stabilize their agricultural base. Wei had the largest population, but throughout the period many of its people continued to flee south to Lu, where the less densely populated regions offered opportunity. But the rich lands in the Yangzi Valley were claimed by strong landlords, and peasants fleeing from the north could usually settle them only if they accepted a status similar to serfdom. Wu also broadened its economic base by a significant enlargement of its overseas mercantile fleet.

The continuing war between the Three Kingdoms came to an end when the northern kingdom of Wei, now ruled by a general who usurped the throne and established the Jin dynasty, conquered the other two kingdoms and united China. The Jin dynasty lasted for a chaotic period of 52 years (265–317), almost constantly at war with one or more of the five groups of Altaic and Tibetan “barbarians” who invaded and eventually erected ephemeral kingdoms on the northern China plain. The Jin government took a census of the united realm; only a few more than 16 million inhabitants were counted. This compares with about 59 million during the heyday of the Han dynasty, indicating the horrendous mortality in the third and fourth centuries.

In the beginning of the fourth century, “barbarian” groups began seizing sections of the northern China plain and settling there as crowds of Chinese refugees fled to the safety of the Yangzi Valley. Xiongnu, Xienbei, Tibetan, and

➤ KASYAPA—A SIXTH-CENTURY BUDDHIST SCULPTURE AT THE MAIJISHAN GROTTOES

In the wake of the collapse of the Han dynasty in 220 CE, a number of smaller kingdoms and self-proclaimed empires appeared in a fragmented China, many of them carved out by non-Chinese invaders. The most important of these invaders were the Tuoba clan of the Xianbei tribe, probably a Turkic people, who established several short-lived but important polities in northwestern China. Of these the Northern Wei (386–535) and Western Wei (535–557) empires were the most significant. The Northern Wei and their Tuoba successors strongly promoted Buddhism as the theological underpinning for their authority, and their patronage of this faith and its arts profoundly affected the cultural course of Chinese civilization forever after. Beginning with the Northern Wei, these foreign empire builders actively supported the earliest construction and decoration of China's four great Buddhist cave complexes at Dunhuang (in the Gobi Desert), Maijishan (near Tianshui), Longmen (near Luoyang), and Yungang (near Datong).

This particular statue, probably dating from the sixth century during either the Northern Wei or Western Wei periods, is found in Cave 87 at Maijishan and portrays Kasyapa, the Buddha's oldest disciple. Together, he and Ananda, the Buddha's youngest disciple, iconographically represented the earliest Buddhist Sangha, or monastic community, and often flanked statues of the Buddha. Note the beaked nose and overall facial features, which clearly mark Kasyapa's foreign ethnicity. The artists who worked in these caves and their Northern Wei and Western Wei

patrons knew that Kasyapa had been an Indian, but he looks central Asian and might well show us a typical elderly Tuoba man.

—Alfred J. Andrea

other bands established short-lived kingdoms in northern China from 304 to 439. Chinese historians call this the Sixteen Kingdoms Period.

By 316, the Jin dynasty was destroyed in the northern capital of Louyang, but in 320 a group of Jin loyalists reestablished the dynasty, now known as the Eastern Jin, near Nanjing. This became the capital of the Southern empire, which extended from the Huai River in the north to the Red River in what is now Vietnam and lasted, in spite of dynastic changes (Liu Song, 420–479; Qi, 479–502; Liang, 502–557; Chen, 557–589) until the reunification of China by the Sui in 589.

Waterways and canals made the cavalry of the northern barbarians ineffective, while the strong navy of the Southern empire offered stout defense and the Southern empire flourished. Over the decades, migration from northern China filled the lands of the Yangzi Valley and pushed south into Hunan and Guangdong. The Southern empire, dominated by wealthy landlord families whose pride was in their northern origins, ensured the continuation of the ancient Chinese traditions and scholarship. The civil service continued to be recruited partly by merit, and the government supported the arts.

Although the rural areas in the Southern empire continued to grow in population and wealth, this did not translate into a strong central government. Powerful families dominated the regions, treating them almost as independent fiefdoms. The decrees of the emperor often did not prevail in the provinces, and the central government's taxing authority was limited. Many powerful families escaped taxation, as did the lands of the growing number of Buddhist monasteries.

In northern China, the "barbarian" kingdoms continued their unending warfare with each other (and with the Southern empire) but began to lose some of their "barbarian" culture and became assimilated into Chinese civilization. In 386 one partly sinified "barbarian" group, the Toba (which may have been Turkish or proto-Mongolian [Xienbei] in origin), seized much of the Yellow River plain and proclaimed the Northern Wei dynasty. In 439, the Northern Wei conquered the rest of North China, establishing what is often referred to as the Northern Empire.

For more than a century, the Northern Wei was a powerful and energetic dynasty. The Northern Wei defended China against the incursions of a new, powerful "barbarian" group, the Juan Juan, so successfully that the Juan Juan abandoned China and turned west. Their descendants, the Avars, would terrorize Europe in the seventh century. The Northern Wei also rebuilt some of the Great Wall and even began to reclaim some of the military colonies established by the Han dynasty on the Silk Roads.

The Northern Wei was able to support these enterprises because of its new policy regarding land and peasants. This policy instituted the Equal Field and the Three Chiefs systems. According to the Equal Field System, peasants were given land in exchange for taxes and labor service. Peasants were supposed to have equal amounts of productive land. In the northern China plain, this amounted to 140 mou, or 19 acres. But the Northern Wei was forced to exclude many estates from the Equal Field system, and as in the south, lands of the great Buddhist monasteries were tax-free. Under the Three Chiefs system, villages were made collectively responsible for taxes. This system divided the

peasants into groups by which the peasants policed each other.

Buddhism made great strides in northern China during the Northern Wei. Northern Wei emperors patronized the Buddhism lavishly, and the great Buddhist cave temples, such as those at Yunkang and Longmen near the two Northern Wei capitals, dug during the Northern Wei, are enduring examples of early Chinese Buddhist art.

Buddhism did not make as rapid progress in the Southern empire, perhaps because of the stronger role that Confucianism played there. Nevertheless, by the mid-sixth century in both the Southern and Northern empires, Buddhism had permeated deeply into the population and enjoyed governmental favor in both empires. In fact, in the Southern empire, Emperor Liang Wudi renounced his throne and entered a Buddhist monastery twice. Government ministers both times were required to pay a high "ransom" each time for his release.

As the sixth century progressed, the Toba rulers of the Northern Wei adopted more Chinese culture. Chinese became the language of court, and Toba officials were required to adopt Chinese clothes, customs, and surnames. Inter-marriage with Chinese families was encouraged.

This court-imposed sinification eventually caused a rebellion among the frontier troops, but the Northern Wei endured until it fragmented into the Eastern and Western Wei in 534. The Northern Qi and the Northern Zhou replaced these two states. In 581, General Yang Qien deposed the last emperor of the Northern Zhou and proclaimed the Sui dynasty, which then conquered the Southern empire, uniting China again.

The Period of Disunity thus came to an end. Although China was to experience more periods of division, none came close to equaling the post-Han Period of Disunity that lasted three and a half centuries. Unlike Europe after the fall of the Roman empire, China after the end of the Period of Disunity was usually conceived of as a single empire.

The Sui Dynasty, 581–617 CE

After the collapse of the Han dynasty in 220 CE, China split into a number of kingdoms. By the mid-sixth century northern and southern China had grown apart culturally and economically. These differences were reversed when the short-lived Sui dynasty reunified China in 581. The unification itself coupled with massive construction projects and the stimulation of economic growth formed the framework for the glorious Tang dynasty that followed.

General Yang Jian, a dynamic man of mixed Chinese and Xianbei descent, took power in a coup d'état in 581. He assumed the title of emperor and ruled as Sui Wendi (581–604). He was followed by his son, Sui Yangdi (605–617). Sui Wendi was lauded as the great unifier, while Sui Yangdi was vilified in the official histories. A close examination of the two reigns shows little difference. Both engaged in enormous engineering projects, and there is little difference in policy between the two reigns. Indeed, many policies of the Sui were continued into the Tang dynasty, where they were praised by official histories.

Reunification helped to solidify Chinese culture and tradition and strengthened the centralized bureaucratic monarchy. The Sui replaced weak governmental institutions with new stronger ones. Laws, rituals, and protocols (*li*) were codified. The Sui revamped local administration to help prevent favoritism. New officials were prohibited from serving in their homelands, and their terms of service were limited to three to four years.

Although the Sui dynasty was sharply criticized for its foreign policy, the same policies were used under the Tang and led to three centuries of peace. The Turks, both eastern and western, and Korea were the primary interests in foreign policy. The western Turks were kept in line because their khan's mother was Chinese and lived in Chang'an, part hostage, part inter-

➤ AN ELEGANT TRIP ALONG THE GRAND CANAL

In 605 the Sui dynasty emperor Sui Yangdi traveled from Loyang to Chiang-tu to celebrate the completion of a section of the Grand Canal linking the two cities. He traveled, along with his court and officials, in specially built boats. All along the 65-mile journey entertainment and provisions were provided by local officials at their own expense. The *Sui History* describes the journey:

“Moreover the emperor caused to be built dragon boats, phoenix vessels, war boats of the ‘Yellow Dragon’ style, red battle cruisers, multi-decked transports, lesser vessels of bamboo slats. Boatmen hired from all the waterways . . . pulled the vessels by ropes of green silk on the imperial progress to Chiang-tu [Yangchow]. The Emperor rode in the dragon boat and civil and military officials of the fifth grade and above rode in the multi-decked transports; those of the ninth grade and above were given the vessels of yellow bamboo. The boats followed one another poop to prow for more than 200 leagues [65 miles]. The prefectures and counties through which they passed were ordered to prepare to offer provisions. Those who made bountiful arrangements were given an additional office or title; those who fell short were given punishments up to the death penalty.”

For a region already staggering from the heavy tax burden and forced labor required to build the canal, this display must have increased local hostility toward Sui Yangdi. Within five years major rebellions broke out throughout China that ultimately led to the fall of the Sui dynasty.

—Rebecca Wendelken

mediary. The Western khan came to Chang'an under Yangdi and remained there until 612.

The eastern Turks were more of a challenge. To control them the Sui began to repair and extend the Great Wall. Wendi kept Turkic children for so-called education, although they were actually held as hostages. Tribes were also resettled

to Chinese territory, and they were kept docile by tribute and payments to prevent them from allying with Chinese enemies. The Chinese used the eastern Turks as mercenaries, although they were not always reliable.

The biggest military struggle of the Sui was against the kingdom of Koguryo. Once a possession of the Han dynasty, Koguryo was rich and already civilized. In 612 China attacked with a two-prong strategy that included land and naval forces. Despite quickly building a bridge over the Liao River, the Chinese were rebuffed by Koguryo's walled cities and by summer rains. The following year the Chinese attacked again but this time were distracted by rebellion at home. In 614 on their third campaign, Chinese troops came within close distance of Koguryo's capital near present-day Pyong-yang, but attempts to convince the king of Koguryo to surrender failed. A fourth campaign was planned but never executed because of a civil war in China. Another campaign against Manchuria, once part of the Han dynasty as was Koguryo, ended in failure. One major success was reconquering Vietnam.

The Sui dynasty is especially known for its construction projects. A new capital, a canal system, granaries, rebuilding the Great Wall, and creating a navy were only a few. Early in the dynasty the Sui began to build a new capital southeast of the old Han capital of Chang'an. Building materials from the old city were recycled to construct new walls, fortifications, palaces, and temples. The capital was erected quickly, and quality was often sacrificed. Many of the walls had to be rebuilt during the Tang dynasty.

The Great Wall was crumbling by the time of the Sui dynasty. The wall was repaired, and more segments were added. The royal libraries were expanded, and unique books in private collections were copied to make the collections of the libraries more complete.

To help unify the northern and southern parts of the country, Wendi began the construction of a canal system to improve China's transportation and increase trade. This Grand Canal was completed by his son. The system was constructed in segments. Existing canals were repaired and widened, and new canals were built. The first canal connected the Wei River near

the capital with the Yellow River, bypassing a section that frequently silted up. Other canals and canalized rivers united the Wei and Yellow River valleys with the Yangtze River. The Grand Canal itself, nearly 1,300 miles long and varying in width between 300 feet (90 meters) in the countryside and 100 feet (30 meters) in the cities, stretched from Hangzhou to Chang'an on to near the present-day city of Beijing. Each canal had post roads running along either side. Huge granaries were constructed near the canals, and some held as much as 33 million bushels of grain. Despite this, very little grain was transported at that time. Most of the river and canal traffic consisted of silk during the Sui dynasty. The canal system was enormously expensive and required heavy taxation and huge amounts of compulsory labor. When males were in short supply, women were conscripted.

In an effort to reunify and harmonize Chinese culture, the government listed proscribed books that were thought to be morally corrupting or subversive. These books were burned. Confucianism was deemphasized under Sui Yangdi, and schools were reorganized. Part of this included changes in writing styles. Governmental writing was ordered to be straightforward without flowery phrases.

High taxes, compulsory labor levies, and flooding in Hopei and Shantung increased peasant revolts in those areas. Sui relations with their Turkic neighbors also suffered, as the Turks were virtual allies of the Koreans. In 613 the Yang Hsüan-kan Rebellion broke out. In 617 rebels led by General Li Yüan, who had been put in charge of destroying them, seized the Sui capital and demanded that Sui Yangdi step down. The new government called itself the Tang dynasty. They renamed Daxing, the Sui capital, reverting to Chang'an, the name used by the Former Han dynasty. The general's son, Li Shih-min, became the first emperor of the Tang.

It is clear that the Sui dynasty laid the groundwork for the Tang in government, foreign policy, and reorganization. Even governmental personnel were transferred from the old government to the new Tang dynasty, which helped provide stability to the new regime. But the Tang realized that the major changes of the Sui had caused dis-

juncture and that China needed a period of healing. Centralization was retained, but Sui tactics that placed intense pressure on the common people were lessened, allowing the new government time to win the people's support.

■ Introduction: Islamic Political History

In the seventh century, the Arab Muslim empire emerged with explosive force and, within a century, became the largest and most populous political entity in world history up to that time. At its height the Arab Muslim empire, or caliphate, stretched from the Atlantic coast of the Iberian Peninsula to the Indian Punjab, and its writ reached into central Asia and the Saharan wastes. The caliphate was the principal political force in the Western Eurasian world for nearly three centuries, from at least 640 to the rise of the Buyid sultans in the 930s. But even though the caliphate lost much of its political power early in the tenth century, it remained an important religious symbol that conferred political legitimacy on aspiring regimes throughout most of the Muslim world until the Mongols destroyed the caliphate itself in 1258.

Islamic political history begins with Muhammad in the city of Medina. From there, the Prophet constructed the first Islamic state, which, by Muhammad's death in 632, included much of the Arabian Peninsula. On Muhammad's death, the Companions of the Prophet chose a caliph (Commander of the Faithful) to rule the expanding state. The first four caliphs, the Rashidun caliphs (the "rightly guided," or legitimate caliphs), were chosen because of their piety and closeness to the Prophet.

During the reigns of the Rashidun caliphs, the Muslim state experienced explosive growth, destroying the Sassanian Persian empire and conquering the wealthiest and most populous provinces of the Roman (Byzantine) empire, but was racked by succession disputes and recurring civil wars (*fitna*) between those who came to be known as Shia and those who were Sunni. The Shia believed that the caliphate should be

conferred on Ali, Muhammad's cousin and son-in-law, and his descendants, whereas the Sunni insisted that the caliph be chosen from the Quraysh tribe by a consensus of the Islamic community. A third, more radical group, the Kharijites, insisted that any sufficiently pious Muslim male could assume the caliphate.

In 661, the Muslim governor of Syria, Muawiyah, proclaimed himself caliph on the assassination of Ali, the fourth Rashidun caliph. Muawiyah founded the Umayyad dynasty, which ruled from Damascus. With the rise of the Umayyads, the office of caliph became hereditary though not in the family of the Prophet. During the Umayyad dynasty, the Arab empire continued to expand. Indeed, it reached its apogee during this period, growing with the conquest of most of Mediterranean Africa (except Egypt, which had been conquered during the Rashidun period), Spain, much of central Asia and the Indian lands of Sind, and the western Punjab. Umayyad armies probed into southern France, and annual campaigns were launched into the Anatolian heartland of the Byzantine empire. Twice the Umayyad forces came close to capturing Constantinople (674–678, 717–718), and in 738 their forces penetrated as far as Poitiers, in the heart of France.

The Umayyad caliphate was powerful and expansive, yet it lasted a mere 89 years (661–750). In its power and arrogance, it scandalized the more pious among the Muslims, and it alienated non-Arab Muslim converts, particularly in Iran and central Asia. Ibrahim, a fourth-generation descendant of Abbas, the Prophet's youngest uncle, was especially alienated. He organized a rebellion against the Umayyads, allying himself with Shias as well as disgruntled Persians.

► CHRONOLOGY OF ISLAMIC POLITICAL HISTORY TO 1000

All dates are in the Common Era (CE).

622–632 — Early Islamic state under Muhammad's rule

632–661 — Rashidun caliphates

661–750 — Umayyad caliphate

750–1258 — Abbasid caliphate

934–1062 — Buyids

Al Andalus to 1000

711 — Islamic conquest of Spain

755–929 — Umayyad emirate of al Andalus

929–1031 — Umayyad caliphate (al Andalus)

Morocco to 1000

744–1058 — Bhargawata

744–974 — Idrisid emirate

800–909 — Aghlabids

909–1171 — Fatimid caliphate

—Wilfred J. Bisson

Although the Umayyads assassinated Ibrahim, his forces destroyed the Umayyads at the Battle of the Greater Zab River and proclaimed Ibrahim's brother Caliph Abbas al-Saffah, the first of the Abbasid dynasty, in 750.

The Abbasid caliphate made their newly created capital at Baghdad (762), which soon became one of the wealthiest and most populous cities in the world. The Abbasid caliphate was not as expansive as its Umayyad predecessor had been. Morocco soon came under the rule of Kharijite and other schismatics: the Bhargawata and the Idrisids. The populous and wealthy province of al Andalus fell under the sway of Abd al Rahman, an Umayyad who had escaped the manhunt following the defeat of the Umayyads at the Greater Zab. Al Rahman set up an Umayyad emirate of al Andalus and defended it against Abbasid attacks. The Umayyads ruled Hispania first as an independent emirate but in 929 declared their rule a caliphate, which endured until 1031.

In the West Asian heartland of the Abbasid caliphate, Abbasid rule remained strong for

nearly two centuries until the Buyid military men took control and reduced the role of the caliphs to that of figureheads. Even before that, Abbasid rule of the further provinces atrophied. In Ifriqiya (Tunisia) the Aghlabids became hereditary independent governors in 800, while the Saffarids and Samanids won the same power in Persia somewhat later. In Egypt, Turkish mercenaries—the Tulunids and Ikshidids—ruled in the tenth century, while in Syria the Hamdanids became hereditary emirs.

Meanwhile, an Ishmaili Shia caliphate, that of the Fatimids, challenged the Abbasids for religious and political leadership of the Muslim world. The Fatimids had originated in Ifriqiya in 909, overthrowing the Aghlabids, who were Abbasid loyalists. Soon the Fatimids conquered all of Mediterranean Africa, including Egypt, where they founded their new capital, Cairo, in 969. Before the end of the tenth century, the Fatimids had seized Palestine and western Arabia, with the holy cities Mecca and Medina, and threatened the Iraqi heartland of the Abbasids. Cairo rapidly became the commercial center of the western world, surpassing Baghdad in wealth and sophistication. In Cairo, the Fatimids founded what many historians refer to as the first university in the western world, Al Azhar, as an institution to teach Shia theology and jurisprudence. The Fatimids reached the height of their power early in the eleventh century. In the middle of the eleventh century, Ifriqiya had become independent and converted back to Sunni Islam. First, Turkish troops and then crusaders drove the Fatimids from Syria and Palestine late in the eleventh century, and in 1169 the Sunni champion Saladin seized power in Egypt, ending the Fatimid caliphate.

The Abbasid caliphate endured as a symbol for Muslim unity but had no political power after the Buyids took power in Baghdad in 945.

Islamic State from Its Inception through the Orthodox Caliphs

The Islamic state took its earliest form in western Arabia around 622 and by the end of some 40 years had spread from Egypt to Iran, had weakened or destroyed two other empires in the Middle East, and had laid the groundwork for a world civilization. Yet Arabia at first glance was hardly an auspicious location from which to conquer, build, and administer a vast empire, inhabited as it was by nomadic, decentralized Bedouin tribes. The rest of the Middle East was ruled by two empires weakened by decades of war with one another, the Byzantine empire in modern-day Turkey, Syria, and Egypt and the Sassanian empire in modern-day Iran and Iraq.

It was in this context in which Muhammad, a merchant in the cosmopolitan city of Mecca, is said to have begun receiving revelations from the angel Gabriel, as the mouthpiece of God, starting in 610. These revelations tasked Muhammad with bringing “true religion” to the Arabs. He was not well received in Mecca, and in 622 Muhammad and a group of followers migrated to Medina, a city about 200 miles to the north. Muhammad had received an invitation to arbitrate a dispute between two prominent Medinan tribes, which he accepted in exchange for a pledge to obey and defend him. The migration from Mecca to Medina marks the first year of the Muslim calendar, and it is in Medina, where Muhammad began organizing a polity, that we find the genesis of the Islamic state.

In Medina, Muhammad strengthened his control by exiling two Jewish tribes and executing the male members of a third who had refused to accept his claim as prophet. Through diplomacy, marriage alliances, and conversion, Muhammad succeeded in winning over the Bedouin tribes into accepting his leadership. Through these efforts, he was able to build over time a faith-based community centered around his role as both political leader and prophet.

It was apparent that Muhammad's efforts to form a new polity were meeting with success when, in 624, the Muslims defeated a superior force of Meccans at the Battle of Badr. By 630, Muhammad had amassed a strong enough force of Medinans and tribesmen to convince the

Illustration from a sixteenth-century manuscript depicting the Battle of Badr, fought in 624 CE between Muhammad and his followers and the Meccans. (Erich Lessing/Art Resource, NY)

Meccans to surrender to him. Muhammad died in 632, having established a Muslim community and cobbled together an alliance from scattered Arabian tribes, yet significantly, he had not provided for a successor, or caliph. When after his death it appeared that the fragile coalition of Bedouin tribes was in danger of disintegrating without Muhammad to unite them, the Muslims chose Abu Bakr, Muhammad's uncle, to succeed him. The function of Abu Bakr and the caliphs who came after him was primarily to run the state, and although their religious prestige heavily influenced whether or not they were chosen, they were not prophets but rather statesmen with religious credentials. Abu Bakr himself was tasked with reestablishing unity over the Arabian Peninsula, which he succeeded in doing through a series of campaigns known as the

Ridda (apostasy) Wars by the time of his death in 634.

Under Umar, Abu Bakr's successor, the Muslims set their sights northward, toward the Byzantine empire, and eastward, toward the Sassanian empire. The purpose of the conquests was not, as is often thought, conversion but rather to collect booty and establish an Arab-Muslim elite over the conquered territories, accomplished by setting up a number of garrison towns (two well-known ones are Basra and Kufah in modern-day Iraq) from which the new elite could oversee the empire and carry out further conquests. The function of the newly conquered lands was, accordingly, to collect taxes and distribute them to the Arab Muslims, the new ruling class. In this capacity, the Muslims benefited enormously from the administrative apparatuses left behind by the Sassanian empire, which had fallen by 651, and by the Byzantine empire, which held on to Turkey but lost Syria and Egypt. By adapting these long-established systems of governance, the Arab Muslims were able to manage their expanding empire with the state apparatuses already in place.

Although Umar had established how the empire was to be administered, the issue of who had the right to administer it became a topic of bitter dispute. Umar had favored the first converts and early allies of Muhammad and alienated the older Meccan and tribal aristocrats. Umar was murdered by a Persian slave in 644. His successor, Uthman, was from an aristocratic Meccan family and was also a companion of the Prophet. Under Uthman's rule the conquests continued, as did the disagreement over power sharing in the empire; while Umar had favored the early converts, Uthman followed an opposite policy, this time favoring the pre-Islamic aristocrats. Moreover, many of the provincial governors resented him for diverting revenue from their districts to Medina, and he was often accused of nepotism. He was murdered in 656 by some Egyptian mutineers.

Ali, the next caliph, Muhammad's son-in-law and an early convert, found himself in the unenviable position of trying to simultaneously propitiate both the pre-Islamic aristocracy and the early converts to Islam as well as a new party led by Uthman's cousin, Muawiyah, governor of

Syria, who demanded retribution for the slaying of Uthman. In the ensuing civil war, Ali's forces met Muawiyah's in a stalemate at the Battle of Siffin in 657. Ali consented to arbitration to address the issue of whether or not Uthman's death was justified. This prompted some of his followers to turn against him for "compromising," and by 659 Ali found himself with few supporters. Rebellions threatened to engulf the empire, unrest threatened tax revenue, and turmoil threatened to undermine security. When Ali was assassinated by one of his disenchanted followers in 661, the Muslims chose Muawiyah as caliph. Whereas the selection of the first four caliphs was influenced by their status in Islam, Muawiyah was chosen because he was the most capable of restoring order. The caliphate became a hereditary office, and the civil war engendered a permanent division of Muslims into two main denominations: the Shia, who look to Ali as the sole legitimate caliph, and the Sunnis, who in addition to Ali recognize Muawiyah and his successors. Muawiyah moved the capital from Medina to Damascus and established a dynasty that would last until 750.

Umayyad Caliphate

The Umayyad dynasty was in power from 661 to 750, a relatively short but formative period, as the Umayyads consolidated Islamic control of conquered lands and adapted the Classical Roman, Greek, and Persian heritages to Islamic civilization. The Umayyad dynasty chose Damascus as its capital and established its presence there with the construction of the great Mosque out of the Christian Cathedral, which had previously been a temple to Jupiter. The Umayyads laid the foundations for Classical Islamic civilization, yet

they, along with the Greek Byzantines and Frankish Carolingians, were also inheritors of the Roman empire that had preceded them. The Umayyads maintained much of the late antiquity Byzantine administrative system that they had inherited. They transformed the caliphate from an elected leader based on consensus to a hereditary monarch relying on a trained bureaucracy.

The first Umayyad caliph, Muawiya (r. 661–680) came to power by defeating Ali, the son-in-law of the Prophet Muhammad, in the first Muslim civil war. Muawiya established his capital in Damascus in Syria, since the earlier capital, Medina, had seemed to contribute to instability, as it was in the midst of the factionalized tribes of the Hijaz while the wealth and power center had shifted to Syria. Muawiya divided his empire into a few large provinces ruled by his closest associates and family members. For local government, he relied on provincial scribes and elites. Through marriage and cooperation, he managed to keep factions and warring tribes at peace. He designated his son, Yazid (r. 680–683), as his successor.

After Yazid's death, civil war erupted again. Marwan I (r. 684–685) was elected by the leading tribe, the Qudaa, and he succeeded in maintaining the Umayyad power base of Syria and Egypt. Ibn-Zubayr, linked to the family of the Prophet, led the revolt and was recognized as caliph by the rebels. However, the opponents to Umayyad rule, although initially successful, were not united. Ibn Zubayr was killed in the siege of Mecca by al-Hadjdadj, who had been sent by Abd al-Malik (r. 685–705), son and successor to Marwan. Abd al-Malik managed to finish the civil war and reconquer Iraq (and to build the Dome of the Rock around 692). He then presided over a period of peace and prosperity. He reformed and formalized the Umayyad administration and taxation, and he also made Arabic the official language of the government. In 744 the caliph al-Walid II was assassinated after being on the throne for only one year. His assassination unleashed a civil war that was not ended until 750 when the Abbasids came to power and moved the capital to Baghdad. However, Abd al-Rahman ibn Muawiya, an Umayyad prince, escaped to Spain and set up the Umayyad caliphate of Cordoba, which presided over a

➤ JOHN OF DAMASCUS

John of Damascus (676–749), a saint in the Eastern Orthodox Church, is a symbol of the early syncretistic character of the Umayyad caliphate. His Arabic name was Yahya Ibn Mansur, and he was bilingual. He was a *wazir* (high official) in the government in Damascus, although he remained a Christian. He was dismissed on account of bureaucratic intrigue, and he retired to a monastery in Palestine where he became known as a great defender of icons. His career is an example of how many Christians actively participated in the life and government of the Islamic empire under the Umayyads while maintaining contact with Christians in the Byzantine empire.

—Benjamin de Lee

great cultural flowering in Islamic Spain. The last Umayyad caliph in Spain ruled until 976.

The territory that the Umayyads were able to conquer was vast. Immediately after the end of the civil war, Muawiya continued his assault through North Africa. By 711 the Muslims had conquered Spain, and by 751 they had reached central Asia and India. Although these conquering armies were initially the great nomadic warriors of the Arabian Peninsula, by the later Umayyad period the caliphs employed professional armies of mixed ethnicities.

The Umayyads were great patrons of art. Their transformation of the cathedral of Damascus into a mosque (709–715) symbolized their synthesis of the classical pre-Islamic Roman and Byzantine heritage with the new religion of Islam. Like the Dome of the Rock in Jerusalem (692), the construction of the mosque relied on Byzantine artisans and utilized Byzantine mosaics and architectural techniques. Early Umayyad caliphs also built numerous desert retreats near Damascus. Many of these pleasure palaces and complexes were masterpieces of early Islamic art, but by the reign of Yazid III (744) such expenditures had depleted the treasury, and he was forced to reside in Damascus.

Although the Abbasids maligned the Umayyads as impious, the foundations of Islamic civilization were laid in the Umayyad period, as Islam came into its own as an organized religion.

Umayyad Mosque in Damascus, Syria. The caliphate of the Umayyad dynasty moved the capital from Medina to Damascus during the seventh-century CE rule of Muawiyah. (Hendrik Dacquin)

Ulama, Islamic scholars, debated and discussed every aspect of Islamic law and life. The *hadith*, sayings of the Prophet, were collected and authenticated. It was also in the later Umayyad period that the major sects of Islam arose, most notably the division between the Shia and the Sunni.

By the end of the Umayyad period, Islamic civilization had developed and advanced far beyond its tribal, militaristic roots. Soldiers, tribesmen, and free people were all subjects of a central government. The Muslims were not an occupying army but were now part of a new culture that had arisen from the collapse and transformation of late antiquity culture.

Abbasid Caliphate to 1000 CE

Ruling large swaths of the central Middle East and Iran during Islam's golden age, the Abbasid caliphate was the major political and cultural center of the Islamic world. Along with China under the Tang dynasty, the Abbasids, during the early centuries of their existence, created one of the most intellectually vibrant, economically prosperous empires that the world has ever seen. The Abbasid caliphate originated when the Abbasid family, claiming descent from al-Abbas, an uncle of the prophet Muhammad, overthrew the Umayyad caliphate (661–750) in a revolution and established what would become the largest Islamic territorial empire in history. Based primarily in the unruly Umayyad frontier province of Khurasan in eastern Iran and the Iraqi city of Kufa, the Abbasids and their supporters built a support base among discontented Umayyad subjects, primarily new non-Arab converts and Yemeni tribes. Publicly sympathetic to claims to political authority by descendants of the fourth al-Rashidun (“Rightly Guided”) caliph, Ali ibn Abi Talib (Alids), the Abbasids stated that they wanted to return the seat of leadership to a member of the Prophet's household. The lack of a specific, widely accepted definition of exactly who was a legitimate successor may explain why the Abbasids were able to elevate themselves to take over the caliphal title and marginalize the Shia.

The success of the Abbasid revolution rested on the military support of soldiers and notables from Khurasan under the leadership of Abu Muslim, who was key to the ascension of Abul Abbas as the first caliph in October 749 and the failure of negotiations by Abu Salama to name an Alid to the position. Khurasani troops defeated Umayyad armies and killed off the majority of the Umayyad men to prevent their return to power. One notable exception was Abd al-Rahman, who fled west to the Iberian Peninsula where he established an

Umayyad state that successfully repelled several Abbasid invasions and ruled al-Andalus until the rise of the collapse of the Spanish Umayyad caliphate in the early part of the eleventh century.

In 762 the second Abbasid caliph al-Mansur ordered the construction of Baghdad, a new capital city, that would serve as their administrative and military base. The new capital was closer to the Abbasid stronghold of Khurasan and signaled a formal end of the Umayyads, whose power was based in Damascus, Syria. Although it had existed as a small town shortly after the Umayyad expansions eastward into Iran, under the Abbasids Baghdad was greatly expanded. Large military bases and residential areas for construction workers were built, as were palaces, government buildings, centers of scholarship, and libraries. At its height, the city was home to between 200,000 and 500,000 residents, making it one of the largest urban centers in the world at that time.

The founding of Baghdad allowed for flourishing of the arts and letters under the auspices of Bayt al-Hikma (House of Wisdom), the imperial library and center of learning that reached its height in the late eighth century into the first half of the ninth century under the caliphs al-Mamun (813–833) and Harun al-Rashid (786–809). Among the most notable Abbasid-era accomplishments were the translations of hundreds if not thousands of Classical Greek, Roman, Persian, and Indian texts into Arabic. When the library was destroyed in 1258 by the Mongols, it was said to contain over 40,000 manuscripts, many of which existed only in Baghdad.

The increasing availability of Greek philosophical texts played a significant role in the emergence of the Mutazilites, a Muslim intellectual movement that argued for a rationalist approach in interpreting religion. Although they believed in the absolute unity of God (*tawhid*), the Mutazilites believed the Quran to have been created, which ran counter to traditional views that it was eternal and held that people possessed free will. Although favored by several Abbasid caliphs during the early ninth century, the Mutazilites became the focus of mounting criticism from more traditional scholars, and by the late twelfth century the movement had died out, though some of its practices were adopted by Shia theologians.

Illustration by al Hariri shows life in Abbasid times, with a camel caravan at an oasis. The Arabic text reads "Oh God, protect my belongings and my destiny. God be my leading power. God be my savior, grant me security and safety, make me choose your path, provide me with health and wealth," Abbasid empire, 750–1258 CE. (Ivy Close Images)

During the early Abbasid period the caliphal government was increasingly centralized as the taxation systems and appointment of judges (*qadis*), which had been left to provincial governors under the Umayyads, became the purview of the caliph and his chief minister (*wazir*). Although there is some debate as to the ethnic composition of the Abbasid movement, recent scholarship suggests that although it certainly received significant support from non-Arabs, predominantly Persian converts, the family itself was Arab in origin. The Abbasids diversified the court elite, bringing in Yemeni Arabs, Khurasani Arabs, and Iranian converts and breaking the monopoly enjoyed by Syrian Arab tribes during the Umayyad period.

Centralized Abbasid power reached its height during the late eighth century under Harun al-Rashid, who also reigned during the most prosperous economic times as tax revenue and foreign trade flowed into Baghdad. Trade routes

were maintained from Egypt in the west to China and India in the east. Gold, silver, textiles, ceramics, and agricultural products were the main items that fueled the Abbasid trade-based economy. Despite revolts against caliphal authority, the government was able to impose its rule over the large settled centers of the empire, though far-flung regions remained difficult to control.

Despite the caliphate's successes, the Abbasids began to suffer succession crises by the early ninth century following the death of Harun al-Rashid, who divided the empire between his sons al-Amin and al-Mamun. Soon after their father's death in 809 the first Abbasid civil war erupted, and even following al-Amin's defeat and death when Baghdad fell to his brother's forces in 813, the strife resulted in the loss of Egypt, Syria, Palestine, and North Africa. Although most of these territories would be returned to Abbasid control, Morocco permanently slipped away. Succession crises came to mark the most significant set of challenges to centralized Abbasid rule, and by the end of al-Mamun's reign the golden age of the caliphate had come to a close.

The end of the civil war also marked the beginning of the domination of the Abbasid military by Turkic officers and slave soldiers (*mamluks*) from central Asia. These soldiers were brought into the Abbasid heartlands because their loyalty at least theoretically rested solely with the caliph since they had no tribal, clan, or family ties to the local Arab and Persian populations. However, the Turkic military came into conflict with the Abbasids' Arab troops and the local population, so in 836 the capital and Turkic garrisons were moved to the town of Samarra north of Baghdad. The political power of these new troops and their commanders steadily increased during the ninth century, and mamluk support became crucial in influencing caliphal succession.

By the mid-tenth century Abbasid decentralization forced the caliphs to cede power to different regional dynasties who ruled in the name of the caliph in Baghdad, including the Ghaznavids in eastern Persia and Afghanistan, the Buyids in western Iran and Iraq, and later the powerful Turkic Seljuks. By the early tenth century the Abbasids were no longer able to monopolize the caliphal title with the foundation of a counter-caliphate by the Ismaili Shia Fatimids in Egypt,

North Africa, Palestine, and Syria. Despite the nominal allegiance to the Abbasid caliphs, many of the regional dynasties took over the reigns of political and military power to become essentially independent states. The once successful Abbasids entered into a steady period of decline brought about by the decentralization of state power and the resulting inability to raise funds to maintain a large loyal army or run a complex bureaucracy as had existed during the empire's golden age. Although the Abbasid caliphs no longer exerted effective political authority, they continued to be left as ceremonial heads of state by successive dynastic states including the Ghaznavids in eastern Iran and the Seljuk in western Iran, Iraq, Syria, and Anatolia.

Al-Andalus—Muslim Spain to 1000 CE

For half a millennium Al-Andalus (Muslim Spain) was the most prosperous, urbanized, and literate region of Europe. The Muslims ruled parts of the Iberian Peninsula for more than 750 years and left behind influences in art, architecture, language, and cuisine that have helped to make Spain the unique country it is today. From the Muslim conquest (711) until 1492, Al-Andalus was the westernmost extension of the Islamic world, and the religious, social, and cultural orientation of the region was toward the east, toward Muslim North Africa and Damascus and Baghdad, and not toward Christian western Europe.

After the Muslim conquest, the conquerors settled down but not amicably. Arab immigrants

➤ MADINA AL-ZAHRA

In 936 Abd al-Rahman III began construction on Madina al-Zahra, a palace-city approximately 3.4 miles outside the capital of Córdoba. Built into the side of a hill, the walled city contained three terraces that separated the royal halls and palaces from the gardens, military barracks, and baths on the second level and the residential area of the service personnel on the lowest level. A palace-city functioned as a permanent royal residence with multiple palaces, baths, and gardens but also urban elements, such as markets, workshops, a prison, a mint, and several mosques. Measuring more than 10.76 million square feet, Madina al-Zahra was the largest palace-city in Al-Andalus. Looted and burned in 1012 during a civil war, the site was pillaged for centuries and today is undergoing excavation.

contested with North African Berbers for favorable lands and government posts. Arabs received the choicest sites, but even among Arabs there was conflict between the North Arabs (Qaysites) and the South Arabs (Yemenites).

In the Middle East a new Islamic dynasty, the Abbasids, defeated the Umayyads of Damascus in 750 and attempted to assassinate the entire Umayyad extended family. Abd al-Rahman I (756–788), a nephew of the last Umayyad caliph, escaped and fled from Syria, eventually traveling across North Africa and into Spain. He established the first independent emirate in the Muslim world (756) with the capital at Córdoba. He and his descendants spent the next 50 years consolidating their hold on Al-Andalus. This struggle was at times fierce. For example, in 777 a coalition of Arab leaders called in the forces of Charlemagne, whose Frankish troops swept into Spain to unsuccessfully besiege Zaragoza. On his retreat through the Pyrenees, Basque mountaineers decimated Charlemagne's rear guard, giving rise to the legend, which is remembered in the French epic poem *Chanson de Roland*.

Despite Viking raids, discontent among Berbers, and religious conflict with Mozarabs (Arabized Christians), Abd al-Rahman II (822–852) enjoyed a relatively stable reign that allowed for development of court ceremonies, increased trade, and a further expansion of the Great Mosque in Córdoba to better accommodate the growing numbers of converts to Islam.

The height of Muslim rule in Al-Andalus came with the accession of Abd al-Rahman III (912–961). Competition for territory and prestige in the Muslim world had increased with the expansion of two other dynasties, the Abbasids in Baghdad, who had displaced the Umayyads 200 years before, and the Fatimids, a Shia dynasty that had arisen in the late ninth century in North Africa. As a result, in 929 Abd al-Rahman III declared himself *khalifa* (caliph) and *amir al-mu'minin* (commander of the faithful), a title that had previously belonged to his Umayyad ancestors in Syria. In addition, continuing a tradition of expressing power and authority through architecture, Abd al-Rahman founded and constructed a palace-city, Madina al-Zahra,

a few miles outside Córdoba, and he divided his time and his administration between these two capitals.

Andalusi civilization reached its greatest expressions to date in this period of the tenth century. The caliph received delegations from the Christian kingdoms in the north of Spain and as far away as the Byzantine empire. The markets of Al-Andalus were renowned throughout the medieval world for their variety and quality of goods. Literature, art, and architecture during this period reached a very high level. Two hundred years later, poets would still sing praises to the accomplishments of the Andalusi Umayyads and lament the passing of a golden age of Muslim rule in Spain.

With Abd al-Rahman's death in 961, the fortunes of the Umayyads began to decline. Although the splendor of the Andalusi court continued for another 30 years, internal problems and political intrigue developed, only becoming more serious with the accession to the throne of an 11-year-old boy, Hisham II (976–1009). Al-Mansur (981–1002) was appointed regent, and grew so powerful that the caliph was merely a figurehead. Berber mercenaries became restless, and a *fitnah* (a civil war or rebellion with religious implications) broke out in 1009. Madina al-Zahra was sacked and destroyed, centralized political authority broke down, and the caliphate officially ended in 1031. Al-Andalus broke apart into a series of tiny kingdoms called *taifas* (party kingdoms).

The Christian kingdoms in the north, taking advantage of the discord among the Muslims, expanded greatly. Although North African Berber empires (the Almoravides and the Almohades) would come to the aid of the Spanish Muslims, and although Al-Andalus would hold on to a portion of southern Spain until 1492, its greatest era was over.

The Aghlabid Emirate

In the ninth century, Ifriqiya (modern Tunisia), the Aghlabid emirate (800–909), became one of the most important states in the Islamic empire because it remained loyal to the Abbasid caliphate. Ibrahim ibn Aghlab, commander of the Abbasid garrison of Tubna, pressured Caliph Harun al Rashid to name him hereditary governor of the Maghreb. Theoretically that included the entire Maghreb, but in reality it was not clearly delimited. In practical terms, it amounted to what had been the Roman province of Ifriqiya. The Aghlabids continued to recite Friday prayers in the name of the Abbasid caliph; they flew the Abbasid colors of black and red; and, most importantly, they continued to send tribute in coins stamped *li-khalifa* (“for the caliph”). That the tribute was intermittent speaks to a high degree of autonomy. Each successive Aghlabid governor petitioned the Abbasid caliph to approve his succession. The Aghlabid state was autonomous “by consent of the caliph,” but one has to wonder if the caliph could have done otherwise. Aghlabid administration was modeled after that of Baghdad. And like the Abbasid caliphate, the state was buttressed by religious law of the Hanifi juridical school, although the Maliki school was rapidly gaining in popularity among the population of Qayrawan and the surrounding areas.

A persistent problem for the Aghlabid rulers was the numerous revolts by the *jund*, the Abbasid military. Ibrahim ibn Aghlab's own power was based on the loyalty of the Tubna garrison; later rulers increasingly depended on their own private slave armies. Some of these slaves were purchased from Africa south of the Sahara, but many were East European Slavs obtained from Italian merchants.

During the ninth century, the Aghlabids developed naval power. By midcentury, Aghlabid fleets dominated the central Mediterranean. Ziadat Allah (r. 817–838), third Aghlabid emir, began the conquest of Sicily with his corsair navy in 827. The Aghlabid conquest of western Sicily,

with the taking of Palermo in 831, occurred relatively rapidly, but subduing the remainder of the island was protracted. The defenders offered stubborn resistance. Syracuse held out for half a century (until 878), and the last Byzantine stronghold was not taken until 902. Even before the Aghlabid conquest of Sicily was complete, their navy seized footholds in southern Italy, with strongholds in Bari and Taranto. Under the Aghlabids and successor Muslim dynasties, Sicily reached a high point of prosperity and culture. They revived the ancient irrigation systems of the island and introduced new crops and industries. Lemons, oranges, cotton, rice, sugarcane, and mulberry trees were introduced. Cotton and silk textile industries flourished, and Sicily became a rich trading center from which “oriental” goods were distributed through Italian merchants from Amalfi, Pisa, and Genoa.

Ifriqiya under the Aghlabids enjoyed a wave of prosperity that persisted well into the eleventh century. Indeed, the Maghreb in general shared in this prosperity. The area of cultivated land seems to have expanded and with it the population. The decayed Roman irrigation systems were rebuilt and improved, and the new crops that the Muslims introduced into Sicily had already been introduced into the Maghreb. The growing trans-Saharan trade brought gold as well as slaves to the Maghreb. The growth of trade with the oases of the Fezzan, particularly Zawilla, yielded a supply of alum, important in the growing textile industry of the Mediterranean basin.

The age of the Idrisids and Aghlabids was a crucial period for the Maghreb because it was from that time that the foundations were laid for the three modern states of the Maghreb: Morocco, Algeria, and Tunisia. Except for the edge of the desert, their boundaries have changed very little since the tenth century.

The decline of the Aghlabids was a classic example of the virtue to corruption story described by Ibn Khaldun; that is, over a number of generations, a tough, disciplined ruling elite became soft and corrupt under the influence of the luxuries of city life. The decline began with the reign of Muhammad II (864–875), who delighted in hunting and the palace life. Ibrahim II (875–902) was a tough ruler but had a wide-

City walls of Sousse on the Mediterranean coast of Tunisia, built by the Aghlabids in the ninth century CE. (Lou Lou Photos)

spread reputation for being cruel and for raising excessive taxes. Within the next seven years, three more rulers contributed to the state of decline and to the collapse of the dynasty with the arrival of the Fatimids.

The Emergence of the Fatimids in the Maghreb

“Wanted dead or alive!” In 905 the Abbasid caliph in Baghdad had put out the word that a dangerous political renegade, Ubayd Allah, the

► THE FATIMIDS COMPETE FOR SIJILMASA AND CONTROL OF THE GOLD TRADE

After Fatimid partisans rescued Ubayd Allah in Sijilmasa, the Fatimids held Sijilmasa for only 50 days. In what had now become a seesaw battle to control the city-state, the people of Sijilmasa revolted and killed all of the soldiers in the Fatimid garrison. The Bani Midrar were back in power. But the Fatimids sent a second army to retake Sijilmasa in 922. This time they chose to rule the city through local clients, a strategy that succeeded for 20 years. In 942 the Bani Midrar, led by a local hero named Ibn al-Fath, regained their independence and maintained it for the next 16 years. Ibn al-Fath challenged the authority of both caliphs, the one in Baghdad as well as the Fatimid caliph in Ifriqiya. He took the title *amir al-mu'minin* (commander of the faithful), a title reserved for the caliph himself. And he took yet another caliphal title, *al-shakir lillah* (the grateful toward God), that he engraved on his coins. But then the Fatimids sent yet another army under the command of Jawhar al-Katib. When Ibn al-Fath heard that the Fatimid army was coming, he fled with his “household, family, children, principle officers; he took refuge with them and all of their treasures in Tasagdalt, a stone fortress some twelve miles from Sijilmasa.” Archaeologists think that Tasagdalt is what people in the Tafilalt oasis today call Jabal Mdaoura (Round Mountain), a rock fortress, today in ruins, atop a lofty mesa located due west of the ruins of Sijilmasa, exactly as the medieval texts describe. Ibn al-Fath was captured by Jawhar’s troops and was taken in chains back to Tunisia. The Fatimids controlled Sijilmasa for another 20 years until yet another superpower, the Umayyads of Cordoba, entered the competition to control the gold route to West Africa.

—Ron Messier

future Fatimid caliph, was on the loose and was heading for Sijilmasa. By the beginning of the tenth century the Abbasids increasingly felt threatened by anti-Abbasid propaganda spread by Shia missionaries called dai. The dai who came to the Maghreb was a man named Abu Abd Allah al-Shii (“the Shia”). Following the pattern of earlier Arab refugees such as Ibn Rustam and Idris I, Abu Abd Allah quickly assembled a

following among locals, raised an army, and overthrew the last Aghlabid ruler. He preached the coming of the Mahdi, the Shia imam Ubayd Allah. The prediction was correct. After Ubayd Allah and his son managed to pass through Egypt in disguise, they arrived in Sijilmasa and managed to remain undetected for four years. When Ubayd Allah’s son performed what seemed like a miracle, causing a spring to gush forth, their cover was blown. The two were arrested and imprisoned. Word got back to Abu Abd Allah’s partisans in Ifriqiya. They rescued Ubayd Allah in 909. The following year Ubayd Allah took the title of caliph in total defiance of the caliph in Baghdad. Medieval sources tell us little about the relationship between Ubayd Allah and Abu Abd Allah, but it must have been tense and competitive. It ended with Abu Abd Allah being executed in 911.

From the start, the Fatimid regime was imperialist. From their base in Ifriqiya, they sent agents out to gather intelligence, and they began to weigh their options. Ibn Hawqal, best known as a geographer, was probably such an intelligence agent. He tells us that “taxes on caravans setting out for the land of the Sudan, as well as tithes, land tax, and old-established dues from what was bought and sold there amounted to a total of about 400,000 dinars and this from Sijilmasa and its district alone,” fully half of what the Fatimids collected from the whole of the Maghreb. The Maghreb was agriculturally rich. It was the breadbasket of the former Roman empire, and the tenth-century Arab geographer Ibn Hawqal confirms that it remained rich. A common theme of historians of the early twentieth century was that agriculture competed with and indeed was constantly threatened by nomadic pastoralism. More recently, however, historians have concluded that except for relatively brief periods of nomadic invasion (e.g., the Bani Hilal), the relationship was more complementary than competitive. Agriculture and pastoralism combined to support industries and long-distance trade, a horizontal east-west trade between the Middle East and Spain and a vertical north-south trade connecting the Mediterranean to West Africa, all supporting a tax structure that made the Maghreb a prize worth fighting for.

Taxes provided much of the revenue needed to finance their conquest of Egypt. The rest came from their control of the routes of the gold trade with West Africa. They conducted no less than five expeditions to control Sijilmasa, which they did either directly or through local clients for most of the first half of the tenth century. The gold coming into Morocco had become such a prize that it was bitterly contested by a second imperial rival, the Umayyads of Andalusia who had also taken the title of caliph. The competition between these two superpowers is dramatically reflected by the production of gold coinage. A peak in production in one regime corresponds to a lapse in production in the other. It seems clear that when one regime controlled the gold routes, it was at the expense of the other.

On their fourth attempt the Fatimids finally succeeded in conquering Egypt in 969. They established a new capital immediately north of Fustat and called it al-Qahira ("the city of victory"). The English version of that is Cairo. The Fatimids continued to control much of the Maghreb through a client Berber tribe, the Zirids, under the leadership of Buluggin ibn Ziri. Buluggin's successor, though, began to conduct himself more and more like an independent prince. The final break between the Fatimids and the Zirids came in 1049 when the Zirid al-Muiz ibn Badis took advantage of a split within Fatimid Shia and declared his independence. The Fatimids retaliated by unleashing a hoard of Arab nomads, the Bani Hilal, that Ibn Khaldun described as a swarm of locusts. The destructive impact of the Bani Hilal is a debated issue. Some see the invasion of the Bani Hilal as the cause of a major upheaval in the socioeconomic structure of the Maghreb. Others argue that increasing instability in the Maghreb following the Fatimid immigration to Egypt opened the door to the Bani Hilal. Either way, what followed was the establishment of a number of independent Berber regimes, leaving the whole of the Maghreb under Berber rule for the first time since the Roman conquest. During the first half of the eleventh century the Berber tribes were once again left to rule themselves until they all fell under the imperial power of the Almoravids of the great Sahara.

Baghdad, 762–1000 CE

From the time of its foundation in 762 to its destruction by the Mongols in 1258, Baghdad was the capital city of the Abbasid dynasty and the symbolic center of Islam. The origin of the name "Baghdad" is unclear. According to most Arabic sources, it is derived from Persian and means "gift of god," but Aramaic and other ancient Middle Eastern inscriptions dating from as early as the eighteenth century BCE provide evidence of a much earlier origin of the name.

After the Revolution of 750, the Abbasids turned away from Damascus toward Iraq in search of a capital to symbolize the new era that they had inaugurated. After careful study, the second Abbasid caliph, al-Mansur (r. 754–775), decided on Baghdad, which was then a small and insignificant Christian village on the west bank of the Tigris River.

Al-Mansur named his new city Madinat al-Salam, or City of Peace, with a reference to verses VI:127 and X:26 in the Quran. It was the official name that was used on documents, coins, etc. The new capital was designed to be the imperial army's base as well as the Abbasids' administrative center. The city's circular form, with the caliphal palace and the Friday, or main, mosque at its center, seems to have represented a new Islamic cosmic order, namely the universal rule and absolute legitimacy of the Abbasid caliph.

However, the form of the Round City might also have followed earlier examples of Persian military camps. New institutions such as the bureau of complaints, the body of advisers, and the office of the chief justice were created to implement the new roles and responsibilities that the Abbasid caliphs claimed as their own. Furthermore, a market supervisor, a police chief, various guilds, and leaders of residential quarters helped regulate life in the new city. Very quickly, though, the confines of the Round City were abandoned, the city walls shifted, and the original Round City became part of a larger and rapidly growing Baghdad. No traces of the Round City have yet been found; thus, most of what we know about the foundation of Baghdad is based on medieval chronicles rather than archaeological evidence.

Baghdad's cultural golden age spanned the ninth to the eleventh centuries. During this period the city attracted representatives of different schools of Islamic thought who discussed divergent ideas regarding theology and rational philosophy. Indeed, Baghdad's sophisticated, indulgent, and sometimes extravagant society developed a lifestyle that did not always accord with Islamic moral principles. The "Big Three" at the beginning of this golden age were Caliph Harun al-Rashid (r. 786–809), immortalized in the *Thousand and One Nights*; his *wazir* Jafar al-Barmaki; and the poet Abu Nuwas (ca. 750–810) whose poetry celebrated wine, extravagance, and breaking away from taboos.

In addition to its deserved reputation as a cosmopolitan metropolis where ideas could be freely exchanged, Baghdad during these years also became a hub for the exchange of goods from across the Islamic world and beyond. Commerce connected Baghdad not only to other major Islamic cities but also to sub-Saharan Africa, China, and regions north of the Caspian Sea that were then becoming more accessible to Muslim merchants. Baghdad, in contrast to the earlier Umayyad capital city of Damascus, reflected a more universal, more "Muslim" concept of the caliphate and not one based on Arab hegemony, thereby mirroring the diversity of the many peoples who had converted to Islam and their various ethnic qualities and cultural achievements.

Ironically, Baghdad's cultural height was accompanied by the early stages of the Abbasids'

erosion of political and religious power. The first centuries of Abbasid rule witnessed a civil war between Harun al-Rashid's sons, al-Amin and al-Mamun (809–813); social tensions between different religious and ethnic groups; and the beginning of territorial decentralization. Caliph al-Mutasim (r. 833–842), in an effort to secure his position, preferred to move, together with his Turkish guard, away from Baghdad to a newly founded military camp in Samarra, which remained the military and administrative center from 836 until 870.

Islamic Rule in Iran and Central Asia, 650–1000 CE

The Islamic conquests define the sharpest periodization in Iranian history particularly and West Asia more generally. Although an underlying tenacious continuity is discernible in the Persian-Islamic ethos to the present, the acceptance of a new religion marked the start of a new order, and it became the basis of a new civilization whose identity, development, and efflorescence, subsequent to enslavement, slaughter, and destruction, were completely remolded. It merits reiteration that its articulation, despite pre-Islamic inspiration, was unassailably Islamic. The Sassanian-Zoroastrian legacy of art, attitude, statecraft, thought, and sophistication—neither fully assimilated nor rejected but always ambivalent—was bequeathed to the Islamic tradition. This became evident in Islam's treatment of Zoroastrians who were expediently, and never unanimously, recognized as *ahl al-kitab* (People of the Book).

Zoroastrianism or Mazdeism, the state religion of its Sassanian upholders (224–651 CE),

eclectically also flourished in Afghan and Transoxianian principalities, which completely collapsed with the Arab conquest of Iran and central Asia. It lacked any recuperative power and, of all religions that encountered Islam, suffered the most. Byzantine Christians could at least count on allies or adherents elsewhere, and Jews, unlike Zoroastrians, had honed bitter survival skills over generations. Islam was to leave Zoroastrianism a remarkable remnant surviving as an officially tolerated minority in both Islamic republics, Iran and Pakistan, where known as Parsis there and in secular India, they have dwindled but remain the most progressive and successful South Asians.

Expansion was enjoined by the injunction of the Quran (9:29). The fanatical fervor of a then-nascent proselytizing cult notwithstanding, the Arab attacks mirrored the Alexandrine invasion where poor but hardy Bedouins, like Macedonians seeking loot and land a millennium earlier, overwhelmed the Persians after two or three decisive battles to set the stage and scope of subsequent events.

Conquest was piecemeal and conversion gradual. During the Umayyad era (661–750 CE), an Iranian convert had to become a *mawla* (“client”) of a tribe and assume a socially subordinate position to his Arab ruler. Thus, the inducement to accept Islam attracted the lower orders such as peasants or prisoners and urban traders, retainers, servants, and tenants who prudently ingratiated themselves with their new masters garrisoned in centers across lower Iraq, southern Fars, and Khurasan, especially the Merv oasis (modern southeastern Turkmenistan). Mass conversion was not actively encouraged, but it became plain to Persians that social mobility and prosperity lay in accepting the colonizer’s creed and standards associated with its way of life. Backsliding was ruled out, for apostasy, then as now, invited death.

Ignorant of running an imperial system, the Arabs delegated the administration to former Sassanian secretaries (*dabiran*), thus establishing Islamic *divans* (chancelleries) whereby Pahlavi records were replaced by Arabic only after 700 CE, and tax collection was delegated to subdued magnates (*marzuban*) and landlords (*dabaqin*). Besides the land tax (*kharaj*), non-Muslims or

➤ ISLAM BESIEGED—AL-MUQANNA, THE “VEILED ONE”

No challenge to early Islam was graver than that of Hashim bin Hakim or al-Muqanna during the third Abbasid caliph, al-Mahdi’s reign (775–785 CE). Hailing from descendants connected to Abu Muslim, al-Muqanna came to regard himself as the rightful imam. Imprisoned in Baghdad, he escaped first to Merv and then Transoxiana, preaching that he embodied the incarnate spirit of Abu Muslim who had succeeded Jesus, Muhammad, and Abraham. His expressly anti-Islamic teachings attracted peasants and superficially Islamized inhabitants among rural fastnesses. Neo-Mazdakite and Manichean notions are discernable, though Muslim accounts are silent about his teachings except that he encouraged promiscuity, abolished property, and invited Qarluq Turks to appropriate Muslim lands and wealth. His revolt (774–779 CE) spread across Shahr-i Sabz, Samarkand, and as far as Termez. He retired to a fortress in the upper reaches of the Kashka Darya (southern Uzbekistan) and, when encircled by Khurasanian forces, committed suicide after instructing that his body be burned to vindicate his divine ascent.

He was eulogized as the Veiled Prophet of Khorasan in Thomas Moore’s poem, *Lalla Rookh* (1813), and fictionalized by Jorge Luis Borges in the short story *El tintorero enmascarado Hákim de Merv* (*Hakim, the Masked Dyer of Merv*), published in 1935.

—Burzine Waghamar

dhimmis (people of the covenant) paid a graded capitation tax deemed degrading and annulled upon conversion. Accounts of collection and treatment were meted out vary temporally, demographically, and provincially. But it affords interesting insights into Arab and early non-Arab Muslim interactions: Umayyads, when saddled with increasing official expenses, refused exemption even upon conversion. Other levies were then extracted from converts to shore up revenue losses, which provoked rebellion.

Resistance and revolts were frequent especially in central Asia, which Arabs pillaged after crossing the Oxus in 653–654 CE. Balkh (ancient Bactria’s capital) was reconquered in 663 CE. Bukhara was overtaken in 674 CE, and Samarkand

was overtaken in 676 CE. A total Arab hold was only established under Qutayba bin Muslim's governorship of Khurasan and the East (705–715 CE). By then, 50,000 Arab colonists were settled in Khurasan, albeit after reannexation. Qutayba had to reassert control over Bukhara in 706–709 CE. Its inhabitants were reported to have recanted thrice after being converted under his order. He next decreed the manumission of slaves upon becoming Muslims, demolition of fire-temples and religious sanctuaries, and the compulsory domiciling of Arabs within Bukharan homes to check them from lapsing. Alienation and civil wars were not restricted to infidels. Disgruntled, marginalized Muslim malcontents, both converts and Arabs, began unraveling the Umayyad caliphate by the mid-740s.

Anti-Umayyad strands including Kharijis, Alids, *mawali* (clients), *dahaqin*, and slaves, collectively flagged under the Abbasid revolt, ousted the Umayyads and orientated the caliphate from Syria to Iraq. Led by Abu Muslim, the Abbasids (749–1258 CE), temporarily amalgamated heterogeneous factions by propagating the prophetic ideal of an egalitarian, universal community. Changes in the social and military structure of the caliphate occurred when Persian consciousness manifested itself through revived Sassanian precepts of kingship and governance: the caliph presided over a hierarchical social order as the Shadow of God.

Social antagonisms resurfaced when disappointed elements, particularly the Shia and Khariji, rapidly realized that promised prosperity and justice were mere Abbasid sloganeering. Reprisals did not even spare allies. Abu Muslim, suspected as a powerful gubernatorial threat, was executed by the second caliph, al Mansur, in 755 CE. Abu Muslim's death instigated a rash of revolts among peasants and extremist sectarians saturated with messianic syncretism. Five uprisings flared between 755 and 780 CE linked to Abu Muslim's memory and seriously tested the Abbasids and Islamic orthodoxy. Such social unrest was not restricted to eastern Khurasan and Transoxiana but also extended to metropolitan Iraq, where the *zandaka* (dualist heretics) and *shuubiya* ("people") were alleged to call for Islam's downfall or belittle its Arab component, respec-

tively. By the time of Harun al-Rashid's accession (786 CE), all Persian provinces were in turmoil.

Several statelets challenged the caliphate in and around the borderlands. Within the hinterlands of Gilan, Tabaristan, Azerbaijan, and Daylam were isolated, independent, princely enclaves practicing heterodox beliefs such as the Bawandids (665–1349) and Musafarids (ca. 916–ca. 1090). Only with the arrival of Zaydi Shia preaching was Islam established around the Caspian littoral in the ninth and tenth centuries CE. The Buyids (932–1062) were Twelver Shia and one of the most powerful dynasties of the Iranian intermezzo (821–1055). They conspicuously imitated Sassanian court etiquette including addressing themselves as *shahanshab* (king of kings). Three minor Iranian dynasts—the Tahirids of Khurasan (821–873), the Samanids of Transoxiana (819–1005), and the Saffarids of Sistan (867–ca. 1003)—mark the Iranian resurgence and drift from caliphal authority. While the Saffarids were the first indigenous Persian rulers, it was the Samanids who ushered the New Persian renaissance in Bukhara to rival Baghdad as Islam's cultural capital. But Arabic poets and scholars were at home in its court, as was Ferdowsi whose lyrical verses crystallized the national legend, *Shahnameh* (*Book of Kings*), in 1009–1010. As Greek civilization was to Christianity, Persian became the cultural vehicle that internationalized Islam from Bosnia to Bengal during the next 18 centuries.

Kharijite and Other Heretical States in the Maghreb to 1000 CE

The Arab conquest of North Africa in the mid-seventh century CE was the most significant turning point in North African history. It set in motion the processes of Islamization and Arabization, defining the two most important characteristics that would overlap the indigenous Berber identity to form a truly unique culture. The process of Islamization was slow, requiring centuries. A hundred years after the founding of Qayrawan, the Arab capital of the Maghreb, only half the families in Ifriqiya had adopted Muslim names. The process of Arabization was slower still.

The conquest imposed Arab Muslim sovereignty over an essentially Berber population. The government consisted of an Islamic judiciary and a pair of ministries to collect taxes and recruit an army. A persistent theme in North African history is continued resistance to central authority by the indigenous Berber population. One aspect of that resistance is the Berber acceptance of Kharijite Islam.

Arab Kharijites had fled to North Africa following the general direction of Islamic conquest, and by the late 730s they dominated the religious and political life of Qayrawan. These Arabs, like the local Berber population, viewed the Umayyad caliphs as usurpers. Kharijite rebellions that started in Iraq quickly spread to North Africa. In 739–740 a water carrier in Qayrawan named Maysara who was a Sufriya Kharijite (the strictest and least tolerant of the Kharijite sects) fled to the northwest, where he led the rebellion in the region of Tangier. After suffering a setback at the hands of the Arab army, Maysara was replaced as Kharijite leader by Khalid ibn Hamid. Khalid defeated the Arab army at the Battle of the Nobles in 741. The rebels then advanced on to Qayrawan, where they

were defeated in 742. The rebels were crushed, but they did not go away. Rebellion in the east (Mashriq) made it impossible for the last three Umayyad caliphs to focus on routing out the rebels of the Maghreb. When the Umayyad dynasty was finally overthrown in Damascus and replaced by the Abbasids in Baghdad, the Islamic hegemony over North Africa (i.e., the sense of belonging to a united Islamic empire) began to deteriorate. A number of independent principalities emerged in the Maghreb.

After the defeat of the Kharijite rebels in Qayrawan, the Barghwata, a group of people from different tribes and even from different tribal confederations, fled to Tamesna, the Atlantic plains between Sale and Azemur. There they formed a sect containing elements of both Sufriya and Ibadi Kharijism as well as the mahdist tradition of Shia. They established a state under a king named Tarif. They were Muslim, but they were viewed by most as heretics. They clung to many customs that did not conform to the true faith. For example, they fasted during the month of Rajab rather than Ramadan. They prayed ten times a day rather than five. When they prayed they moved their heads without prostrating. They were permitted to marry as many wives as they wanted but were prohibited from marrying their cousins. They could repudiate and take back their wives 1,000 times a day if they wished, as women were not protected under their law. Rather than cut off the hands of thieves, they killed them. They could neither kill nor eat cocks because these announced the morning prayer; if they did, the penalty was to free a slave. They recognized Salih ibn Tariq as their prophet, and they had their own Quran, in their Berber language, that had 80 chapters named after Adam, Job, Noah, Moses, Aaron, Asbath, the 12 tribes, the cock, the grasshopper, the camel, and the wonders of the world. What this all represents is a genuine Berberization of Islam.

What is most remarkable about Barghwata is its longevity; the kingdom lasted from the middle of the eighth century to the middle of the twelfth. They survived attacks by the Idrisids, Fatimids, Zirids, and Almoravids. And even though these were all setbacks, it took the aggressive Almohads to finally eliminate them.

➤ WHO ARE THE BERBERS?

Although not definitive, perhaps the safest indicator of who the Berbers are is the language that they speak. People who speak a Berber language as native speakers are Berbers.

That is how Ibn Khaldun, the famous fourteenth-century thinker and writer from Tunisia, defined them. He divided the numerous Berber tribes into three major tribal confederations: the Zanata, Masmuda, and Sanhaja. But he ultimately distinguished Berbers by the language they spoke, referring to an ancient king, a contemporary of Moses, who gave them the name “Berbers” when he heard their jargon and asked what that *barbara* was. (Some modern Berbers prefer to be called Amazigh and maintain that the term “Berber” is fundamentally pejorative.)

This seems straightforward enough, but there is a certain amount of cultural baggage that comes with Ibn Khaldun’s definition. Berbers, says Ibn Khaldun, lack “taste,” which he defines as “the tongue’s possession of the *habit* of eloquence” or “the conformity of speech to the meaning in-

tended,” in other words, language. Since the language of culture and authority in the Maghreb under Islamic rule was Arabic and since Berbers did not speak Arabic as a native language, they lacked taste. And Arabs looked at them disparagingly for that. Not only did Berbers lack taste, but there was something inherently rebellious about them. The conquest of North Africa by the Arabs was one of the longest and bloodiest episodes in the extraordinary expansion of Islam. Another early Arab historian, Ibn Abi Zayd, says that the Berbers of North Africa revolted 12 times before they accepted Islam. Ibn Khaldun says that even after the Muslim religion had been established among them, “they went on revolting and seceding, and they adopted dissident (Kharijite) religious opinions.” He adds that this is what is meant by the statement that Ifriqiya (the medieval name for what is now Tunisia and eastern Algeria) divides the hearts of its inhabitants. The statement is a play on words connecting Ifriqiya with the Arabic root *f-r-q* (“to divide”).

—Ron Messier

There were two successful attempts to form independent Kharijite states in the Maghreb. In 757 CE Abul-Qasim Ibn Samgu fled religious persecution in Qayrawan, escaping to the Tafilalt oasis in southern Morocco, the very edge of the Islamic frontier, where he gathered a following among the Bani Midrar tribe. Together they founded the city of Sijilmasa, steeped in the ideology that every believer who was religiously and morally irreproachable was eligible to be ruler “even if he were a black slave.” Indeed, the first ruler chosen in Sijilmasa was Isa Ibn Yazis al-Aswad (al-Aswad meaning “black”). The Midrarid state would last the next 200 years until it was taken by the Fatimids. Its position at the head of the trade routes across the Sahara from West Africa placed it in an ideal position to control, or at least profit from, the flow of West African gold into the Muslim world. The discovery in 1992 of 32 gold coins in Aqaba, Jordan, of which 29 were minted in Sijilmasa in the name of the Umayyads, is testimony to the role

of Sijilmasa as the link between the Islamic and Mediterranean worlds to the sources of gold in West Africa.

The second Kharijite state was in Tahart (six miles west of Tiaret in present-day Algeria). Abd al-Rahman Ibn Rustam, a Persian who had grown up in Qayrawan, had become the Kharijite subgovernor. But when the Abbasids retook the city in 761 CE he was forced to flee. He fled to Tahart and allied with local Berber tribes who, within 15 years, recognized him as Kharijite caliph of an independent city-state that would last until 908, when it too fell to the Fatimids. The Rustamids were Ibadi Kharijites, the more moderate Kharijite sect. In practical terms, that translated into a much more moderate approach to non-Kharijites. The population of Tahart included many non-Kharijites, even some Christians; and many more came to the bustling commercial bazaars of Tahart. The Rustamid state placed enormous emphasis on economic contacts with West Africa. Rustamid merchants

established partnerships with trading firms in the sub-Saharan city of Gao, some Rustamids taking up permanent residence there. Ibn Rustam even married off his daughter to the ruler of the commercial city of Sijilmasa.

The Idrisids of Morocco— An Early Shia Kingdom

The Idrisids, who ruled much of Morocco for nearly two centuries (788–974), established the first independent Arab state in the Muslim Far West and are often hailed as the founders of the Kingdom of Morocco.

By the 780s Shia propaganda had begun to spread concurrently with Kharijism in northern Morocco. The Berbers, faithful to Islam, were impressed that Idris was a direct descendant of the Prophet. Being fiercely independent, they endorsed Idris's opposition to the Abbasid caliphate. In 788 Idris settled in Volubilis, where we see continuous archaeological evidence of urban occupation after the Roman occupation, right up to the founding of the new Idrisid capital city. Idris consolidated his authority over the northern part of Morocco (essentially what had been Mauritania Tingitana under the Romans, along with the Atlantic coastline south of Salé).

Idris died in 791. His infant son was recognized as his successor but was obviously not

able to claim real authority right away. When he was still quite young, in 808, because of perceived dangers of remaining in Volubilis, Idris II established a brand new capital city in Fez. It was in an ideal location at a crossroads going from east (Salé) to west (through the Taza Gap to Qayrawan) and from north (Tangier and Ceuta) to south (Sijilmasa, a new Kharijite city, already a commercial entrepôt on the edge of the Sahara). Fez was to become the nucleus of a sense of political cohesiveness that, after going through several variant phases, would gradually emerge as Morocco. Fez became an important center of Arabization for Morocco. The university there claims to be the oldest in the world. In subsequent eras, refugees from Spain and Qayrawan settled in Fez, making it the cosmopolitan crossroads of the Islamic Far West.

The early Idrisids were active warriors. Through a protracted series of military actions, they conquered much of the region of the High Atlas as well as other Muslim areas. Morocco became an important regional power as well as a cultural center.

The Idrisid state was rudimentary at best. It amounted to little more than a locally recruited army that produced revenues for the regime from spoils of war and by collecting taxes from non-Muslims. The Idrisids were almost totally dependent on the Berber tribes who had adopted them. The Idrisids were Shia, though a large percentage of their Berber subjects were Kharijites, while the populations of Fez and other cities were largely Sunni. The prevailing system of Islamic jurisprudence, at least in the capital, was Malikite, a very strict interpretation of Sharia.

Idrisid Morocco shared in the wave of prosperity that swept over the Maghreb in the ninth and tenth centuries. This prosperity was agriculturally based, stimulated by the revival of irrigation systems and expansion of cultivated land. Sugar plantations were established, and Asian crops, such as citrus fruits, cotton, and rice, were introduced to feed and clothe the growing urban populations. The burgeoning trans-Saharan trade stimulated handicraft industries.

When Idris II died in 826, Idrisid domains were divided among nine claimants within the

family. Succession continued to pass from one to the next, exercising at least nominal control over the dynasty until the Fatimids took Fez in 920. The Idrisids survived in the Riff Mountains, sometimes as clients of the Fatimids, sometimes as clients of the Umayyads of Cordoba, chief rivals of the Fatimids.

■ Introduction: Political History of India

The political history of north India during 300–1000 is highlighted by two major historical narratives, that of the Gupta and the Harsha Vardhana empires and the tripartite struggle for dominance of the Ganges Valley, centering around the city of Kannauj between the Pratihara empire, the Pala empire, and the Rashtrakuta empire, while the political history of the Deccan after the decline of the Gupta empire is taken up with the fortunes of the Chalukyas of Badami, their overthrow by the Rashtrakutas, and then the rise of the Chalukyas of Kalyani or Western Chalukyas (who may or may not have descended from the Badami Chalukyas). The political history of the Tamil southern tip of India is even more complex, involving shadowy warfare and political conflict among the Pallava, Pandya, Chola, and Chera empires.

The Gupta empire (280–550 CE), which dominated northern India, particularly the Ganges Valley, is remembered as existing during a cultural florescence that rivals Greek civilization in the fifth century BCE, or the European Renaissance. It was not a centralized empire, as was the Mauryan empire, because local governments and local rulers were probably more autonomous, causing some historians to refer to it as quasi-feudal.

The Gupta empire's decline started in the middle of the fifth century, when Hephthalite (Huna, or White Hun) incursions sapped the Gupta's strength. By 550, even though the Hephthalites had been defeated, the weakened Gupta empire collapsed into its quasi-feudal components. Nearly half a century after the Gupta collapse, Harsha Vardhana united the Ganges Valley and, in 606, was acclaimed emperor at a great council. He was only 16 years of age. Harsha rule, filled with many wars, lasted until 647, during which time he conquered territory from Gujarat to northern Bengal. On Harsha's death, his empire separated into several small kingdoms.

In the period of the eighth through the tenth centuries, northern India witnessed the sway of two large empires as well as many smaller kingdoms. In Bengal there was the Pala empire, which began when its first ruler, Gopala, was elected by democratic process to the office of Pala, or Protector. The Palas ruled Bengal for 400 years, during which time literature, culture, and prosperity flourished. During the first half of the ninth century, the Pala empire held sway over much of India, including most of northern India. After 850, Pala power retreated to Bengal and Bihar.

The Pratihara empire was the other major power in northern India in the eighth through

tenth centuries. The Pratiharas were Rajputs, but their home ground was Gujarat. In the late eighth century, the Pratihara empire expanded to include most of the Ganges Valley but came into conflict with the Pala empire and retreated. Toward the middle of the ninth century, the Pratihara pushed the Palas out of most of the Ganges Valley, and their empire again ruled most of the Ganges Valley until 910.

In the Deccan (central India), the Chalukya dynasty created an empire that endured for more than 200 years (543–753). They were powerful enough to stop the southern expansion of Harsha's empire in the early seventh century but were defeated by another central Indian dynasty, the Rashtrakutas, in 753.

The Rashtrakuta empire included, at times, most of west-central India to Maduri. During the ninth century, the Rashtrakutas contested the rule of the Ganges Valley with the Palas and the Pratiharas. The Rashtrakuta empire lasted until 982.

In southern India, the Pallava empire dominated from the late sixth century until the early eighth century. During their rule, the great rock sculptures of Mahabalipuram were carved. Their rule saw the beginning of the florescence of southern India culture. They were very warlike and fought the Chalukyas to the north and the Pandyas and Cholas on their southern boundary. For much of the period of their ascendancy, they shared the southern part of the peninsula with the Pandyas and Cholas, but by the middle of the ninth century the Cholas decisively defeated them and established a great empire that dominated southern India, Sri Lanka, and the Bay of Bengal and had great influence throughout Southeast Asia until the end of the thirteenth century.

> POLITICAL CHRONOLOGY OF INDIA, 300–1000 CE

All dates are Common Era.

North India

Third–fourth centuries	Indo-Sassanian kingdom in Punjab
208–550	Gupta empire
590–647	Harsha's empire
711–738	Arab conquest of Sind and Multan

ca. Eighth–tenth centuries	Three-way struggle for supremacy in Ganges Valley
ca. 580–ca. 1000	Pratihara empire
750–1174	Pala empire Bengal's golden age

The Deccan (Central India)

543–753	Chalukya empire
ca. 550–973	Rashtrakuta empire
973–ca. 1180	Chalukyas of Kalyani

South India

571–750(?)	Pallava kingdom
ca. 525–ca. 890	Pandyan kingdom
ca. 850–1275	Chola empire

Harsha's Empire and Feudalism in North India, 600–1000 CE

Harsha, also known as Harsha Vardhana, is regarded, along with Ashoka and Akbar, as one of the great emperors of Indian history. After the decline of the Gupta dynasty, the second great empire after the Maurya to unite much of the Indian subcontinent, Harsha succeeded in developing a large and prosperous kingdom in which education and culture were able to thrive. The period of Harsha's reign is also one of the best documented in ancient Indian history, being covered in great detail in two texts composed during his time: the *Harsha Charita*, or biography of Harsha, written by the Sanskrit poet Bana, and the travelogue of Xuanzang, a Chinese Buddhist monk who traveled extensively in India during Harsha's reign, writing in vivid detail about India's natural features, society, and forms of political administration.

One reason for Harsha's success was his own longevity. A talented administrator, he was able to oversee his kingdom for 41 years, ruling from 606 to 647 CE. He died without an heir, however, and did not leave a very strong administrative structure to succeed him either, relying largely on his own talents and the force of his personality to rule his kingdom. It therefore suffered the same fate as many other Indian empires and disintegrated into a number of small kingdoms after his death.

Harsha hailed from what is now the state of Haryana, in northwestern India, from the city of Thanesar. The story of his ascent to the kingship reads like a great novel. He was the younger brother of Rajya Vardhana, ruler of the Vardhana dynasty, one of many small feudal kingdoms in northern India after the collapse of the Gupta dynasty. Rajya's and Harsha's sister, Rajyasri, was married to a king named Grahavarman, who was killed by a king named Devagupta, of Malwa, in central India. After he killed Grahavarman, Devagupta had Rajyasri imprisoned.

Shashanka, the king of Gauda, in the eastern part of India, agreed to meet with Rajya Vardhana in order to make an alliance with him against Devagupta and help to free Rajya's sister. But Shashanka had already secretly allied himself to Devagupta and killed Rajya Vardhana. Vowing to avenge his brother and free his sister, Harsha raised an army and marched against Devagupta, whom he defeated and killed in battle. Devagupta's people then made Harsha their king. All of this happened in 606 CE, when Harsha was only 16 years old.

Despite his youth, Harsha was a great warrior and administrator. Still determined to punish Shashanka's treachery, he continued his campaign against Shashanka's realm, conquering much of the Ganges Valley in the process. Though he never succeeded in either killing or overthrowing Shashanka, he did outlive him. Bhaskaravarman, Harsha's ally, managed to conquer what remained of Shashanka's kingdom after Shashanka died in 625 CE.

Like Ashoka and Akbar, Harsha practiced a policy of tolerance toward all of the religions practiced in his realm, giving patronage to Buddhism, Jainism, and the various Hindu sects. Religiously speaking, Harsha himself came from a

Shaiva Hindu family. But he was also a generous patron of Buddhism, particularly of Mahayana Buddhism. In Xuanzang's account, Harsha's conflict with Shashanka is cast as a religious war between Buddhism and Shaiva Hinduism, with Shashanka presented as a persecutor of Buddhists and Harsha depicted as their champion. Scholars suspect, however, that this is a biased account, given the prevalence of mixed religious allegiances in ancient India. Harsha continued to support Shaivism while also supporting Buddhism, and some of the most prominent Buddhist educational institutions in India were in Shashanka's kingdom. A play written by Harsha, *Nagananda*, reflects Harsha's mixed religious allegiance. The play is essentially a Buddhist one, being a retelling of a *Jataka* tale, or story of one of the Buddha's past lives. But Harsha makes the goddess Gauri, the wife of the Hindu deity Shiva, a prominent figure in his play, an incorporation that is his own innovation.

As can be seen from the fact that he wrote plays, Harsha was a great patron of the arts in addition to being a great warrior and a capable administrator. After expanding his kingdom through conquest, he moved his capital from the relatively remote Thanesar to the more centrally located city of Kanauj, in the Ganges River valley.

According to most historians, the chief flaw of Harsha's reign was the fact that he relied so much upon himself to administer his kingdom. Without a strong administrative structure or an heir to succeed him, his kingdom quickly collapsed after his death.

The aftermath of the collapse of Harsha's kingdom follows a pattern that can be seen repeatedly in Indian history and that is evident in the aftermath of the collapse of other empires, such as those of the Mauryas, the Guptas, and later the Mughals. Due to the strength of the Indian social structure, in the form of the caste system, the integrity of Indian society is not dramatically affected by such political collapse. Brahmins continue to perform rituals. The mercantile communities continue to trade, and the manufacturing communities continue to weave, make pottery, and so forth. And lower castes continue to perform menial tasks. So, although there is some disruption, the collapse of an empire such as Harsha's does not produce the kind

of social chaos left in the wake of, for example, the fall of the Roman empire. But a situation emerges in which India is divided into a great variety of small kingdoms and subkingdoms in a state of perpetual instability as competing kings vie to become the next Harsha or Chandragupta.

Kingdoms of South India

South India, from 300 to 1000 CE, was never ruled by a single state or empire. Its topography made centralized control difficult. Much of it is characterized by rugged hills and (until modern times) thick jungles. The semiarid Deccan Plateau of central India and the rich but narrow valleys of the Far South seemed unable to sustain large empires or large cities such as those of North India. These were the core areas of the kingdoms of South India, which rose and fell over the centuries in kaleidoscopic patterns.

In the Far South, the traditional dynasties and their core areas were the Cholas in the Cauvery River valley and adjacent coast, the Pandyas from the Madura area to the southern tip of India, and the Cheras or Keralas from the mountain range of the Western Ghats to the Arabian Sea coast. Their age is uncertain, but they existed in the third century BCE, when they are cited in Ashokan inscriptions. On the Deccan, the oldest verifiable dynasty was that of the Satavahannas or Andhras, who apparently dominated politics from the third century BCE to the third century CE. This hilly plateau area was invaded from time to time by rulers to the north and south, and at other times its monarchs invaded and defeated those neighbors. Frequent warfare was the anticipated pattern.

The first historically known monarch was Karikala, who began a period of Chola dominance starting in about 190 CE. Heroic tales are

told about Karikala, whose forces trounced his allied enemies in at least two major battles. He is also supposed to have reclaimed forest lands, created a riverine irrigation system, and patronized elegant poetry. However, the third century CE saw the rise of the rival Pandyas, whose most renowned king was Nedunjelidan.

➤ KERALA—A DIFFERENT INDIA

Kerala is different from the rest of India. Occupying the Arabian Sea coastal strip and resembling palm-clad tropical islands, it is divided from the rest of India by the rugged mountains of the Western Ghats. They could be penetrated by determined settlers, merchants, or even armies, but their semi-isolation allowed the peoples of Kerala to develop their own language (Malayalam), culture, caste structure, and politics. Even its elaborately stylized dance form, Kathikali, is unique.

The Chera or Kerala monarchs supposedly ruled this land from antiquity. They were mentioned in Ashokan inscriptions (third century BCE) and celebrated in many songs and stories. But Cheras may have been a generic rather than a family name, as different lines of rulers took the title. The first such recognized line was the Kulasekharas (800 to 1100 CE). Even then, most real authority resided in the rival city-states that dotted the coastline. This was briefly interrupted by the Chola invasion from Tamilnad in the eleventh century.

Because of its location, Kerala received frequent visitors, including travelers such as Marco Polo, missionaries, and traders. The export of black pepper, ginger, cinnamon, and other spices as well as pearls and cotton cloth propelled the economy. The presence of ancient Greek and Roman merchants has been documented with written references and caches of coins. Persians and Arabs came next and, in a later age, Chinese. According to Christian tradition, the apostle Thomas was sent to India to evangelize, and he arrived at Kerala's port of Cranganore. A Christian community has lived in Kerala since 345 CE, if not earlier. A Jewish community received a land grant in the tenth century. Muslim Arab traders settled in the eighth and ninth centuries, and their descendants (called Mappilas) remain a vigorous part of the diverse society of modern Kerala.

—Edwin Hirschmann

Although the names of such kings are known, the monarchs of South India were unusually restricted in their powers and political roles. A South Indian kingdom has been called a segmented state in which functions were prerogatives of the crown elsewhere here devolved upon others. Thus, according to inscriptions, there were troops of soldiers raised and maintained by assemblies of merchants and areas in which civil governance was assumed by villages of Brahmans (the *brahmadeyas*). Moreover, royal strength often depended on the loyal support of feudatories, powerful local chiefs who might play their own games of power politics. The king had a valued ceremonial role; he was the upholder of *dharma* (the divinely decreed law and social order) and the dispenser of justice. He was expected to defend the society against invaders and outlaws and to attack weaker neighbors, which meant that he needed a fighting force. But his was a hollow crown.

The king was usually assisted by members of his royal family, although family feuds and succession disputes sometimes interfered. He had advisers in such specialized areas as revenue, military, judicial, and theological matters who sometimes became powerful hereditary officials. However, there is no evidence of a regularly constituted council of ministers. There were the equivalent of sheriffs to enforce royal decrees and bailiffs to enforce judicial ones. These depended on the cooperation of village

leaders since the integrated nuclear village was South India's basic socioeconomic unit.

Within this framework, states and dynasties rose and fell. In fragmented central India the most prominent after the fall of the Satavahanas in the third century CE was the Vakatakas, with headquarters near modern Nagpur. A royal marriage to Chandragupta II, ruler of North India, brought them briefly into the orbit of the Gupta empire, but they reigned into the mid-sixth century.

Next to dominate the Deccan was the Chalukyas of Badami (or Vatapi), beginning in the sixth century. Their most accomplished ruler was Pulakeshin II, who won the throne by defeating his uncle, Mangladesha, in a hard-fought civil war. Pulakeshin subdued imperial tributaries who had broken free during the fighting, then defeated the mighty emperor of the north, Harsha, in a crucial battle at the Narmada River in about 612 CE. Pulakeshin had a navy to battle coastal enemies, sent an ambassador to the court of Persia, and received a visit from the Chinese monk Huen Tsang who vividly described this powerful and bellicose kingdom. He later moved south and conquered the Pallavas of Kanchi (near modern Madras/Chennai). However, Narasimhavarman I, son and successor of the vanquished Pallava ruler, retaliated in about 630 CE, defeating the Chalukya armies and apparently killing Pulakeshin.

Those Pallavas rose in the sixth century CE and dominated regional politics in the seventh and early eighth centuries. Inscriptions indicate that this was a period of growing Sanskrit and North Indian cultural influence. The empire peaked with its wars against its longtime Chalukya enemy, resulting in Pallava ascendancy in South India, construction of the port at Mahabalipuram with its rock-cut shore temples, and the spread of South Indian trade and culture across the Bay of Bengal. But the Pallava empire was smashed in about 730 CE by the revived Chalukyas, allied with some unhappy feudatories. The Pandyas then dominated the Far South until the rise of the greatest of all South Indian dynasties, the imperial Cholas, in the tenth century.

In the Deccan the Chalukyas were ousted in the mid-eighth century by the dynasty called Rashtrakutas. This was apparently a clique of provincial officials rather than a kinship family,

Shore temple at Mahabalipuram, Pallava dynasty, seventh century CE. (Infocus/Dreamstime)

and internal factions, rifts, and rebellions were more frequent than usual. Nevertheless, the Rashtrakutas were a restless and ambitious dynasty. Govinda III became the first southern ruler to invade North India, and in 802 he briefly held Kanauj, Harsha's old capital. Several monarchs took the Rashtrakutas south, invading the lands of Pandyas and Pallavas. The dynasty peaked with Amogavarsha (814–880), who suppressed rebellions, spread his domain, built an elegant palace, and became known for his literary and religious pursuits. But offstage the Chalukyas were regrouping, and in the mid-tenth century they regained royal power.

The Pala Dynasty of North India

The Pala dynasty ruled the northern and eastern Indian subcontinent, coinciding with present-day Bihar, West Bengal, and Bangladesh, between circa 750 and circa 1174. The Palas rose to power during a period of anarchy following the decline of the Guptas and repeated foreign invasions. During their reign, Bengal achieved its highest level of power and cultural achievements. The Palas were prominent promoters of Mahayana Buddhism and patronized the arts and architecture. They are held responsible for the reformation of Buddhism in Tibet. Their art, known as the Pala School, had a long-lasting impact on the arts of Tibet and Southeast Asia. The dynasty was eventually replaced by the Hindu Senas toward the end of the twelfth century.

The founder of the dynasty, Gopala (ca. 750–775), brought an end to the so-called Dark Age of Bengal, referred to by the Tibetan historian Taranatha Lama as *matsyanyan*, or "eating of small fish by big fish." According to some historians, Gopala was democratically elected by the desperate people of the city of Gaur in Bengal to end this anarchy and restore peace and wealth to the country. From ancient sources it appears that Gopala was not of noble origin but instead was the son of a warrior, a *shudra* (member of the working class), or a *kayastha* (scribe) and perhaps the grandson of a learned man. Not much is known about his life and career, but it is generally agreed that he ruled all of Bengal.

The second in line, Dharmapala (ca. 775–810), is better known and is considered one of the greatest kings of Bengal. His name means "Protector of the Law," perhaps as a reference to the eight fierce Buddhist deities whose task it is to protect the Buddhist law. He expanded the Pala reign into the Deccan and the Gangetic plain up to Kanauj, notwithstanding a continuous struggle for supremacy with the Gurjara-Pratiharas of Rajasthan and the Rashtrakutas of the Deccan. Mutual conflicts between the Pratiharas and the Gurjaras indirectly helped Dharmapala in gaining full control over Bengal, Bihar, and Kanauj. Several Rajput rulers had to pay him tribute. Dharmapala founded the university and monastery at Vikramashila.

Dharmapala's son, Devapala (ca. 810–850), is believed to have extended the boundaries of his kingdom even farther to Pragjyotisha (Assam) and the Vindhya range in the south, although not much is known about the details of his military campaigns under his cousin General Jayapala. Some historians assume that Devapala even conquered Kamboja, a region in ancient Gandhara (Pakistan-Afghanistan). Unfortunately, no details of this extension are available from ancient sources other than vague evidence provided by the fact that Devapala appointed Viradeva from Kamboja as abbot of Nalanda. According to Taranatha Lama, Devapala founded the Great Monastery at Somapura, known as Sompur Bihara. The reign of Devapala saw the maximum expansion of the Pala realm. After him, larger and smaller areas were gradually lost, and the kingdom survived in a reduced form.

THE PALA SCHOOL OF ART

The name of the Pala dynasty survived in their art, generally referred to as the Pala School of Sculptural Art. Pala art had a lasting influence on the Buddhist art of Sri Lanka, Nepal, and Southeast Asia. Their main products were in bronze and black stone and reveal a high technical standard. Pala bronzes were usually gilded and often inlaid with silver. A new invention was the crowned Buddha. Although these gilded bronzes are predominantly Buddhist, the earliest dated Hindu bronzes were produced by the Palas as well. Pala stone sculptures are carved out of fine-grained black schist from the Rajmahal Hills (Jharkhand) and are often polished. The portrayed figures are somewhat more sensual than in the preceding Gupta art. Females invariably have heavy round breasts and bulging hips, whereas males have broad shoulders and narrow waists.

A change through time is observed within Pala sculptural art. Gradually, the bodies became longer and more static, the faces more pointed, and dresses, jewelry, and background figures more finely carved and complicated. Typical for the later period are huge steles portraying the Hindu god Vishnu with his two spouses, crowded with a multitude of minor figures and traditional background decoration around the central image.

—Alexandra van der Geer

Mahipala I (ca. 995–1043) reestablished Pala supremacy in large parts of Bengal and Bihar. He is considered the second founder of the Pala dynasty. The kingdom was confined to southern Bihar under his two immediate predecessors due to repeated invasions by Chandellas and the Kalachuris, two Rajput groups that arose after the demise of the Pratiharas. Toward the end of his reign, Mahipala had regained northern Bihar. The main temple at Paharpur was renovated, and architecture was added under his patronage. He is also credited with having constructed and rebuilt religious architecture at the Buddhist pilgrimage center Sarnath. Songs about the deeds of Mahipala survived to the present time.

Copperplates and other ancient sources indicate that Mahipala I reconquered his paternal

kingdom, which had been taken away from him by people who had no claim to it. Two opinions prevail about the exact nature of this statement. The earlier theory holds that foreign tribes or war bands had come and set foot in Bihar, usurping the Pala kingdom. The later theory holds that there was a conflict within the Pala lineage itself and that it had split in two. The occurrence of exactly the same names of kings and their epithets but in different genealogies is evidence for this. In addition, the referred kings belong to the same era and time frame.

During the Pala reign both Mahayana Buddhism and Hinduism flourished. Religious and artistic ideas were exported to Nepal, Tibet, and Southeast Asia. The vast production of artworks is explained as thanks to the relative peace and religious tolerance. The Palas founded many monasteries and enlarged existing ones. During their reign the universities of Vikramashila and Nalanda, the largest Buddhist universities ever, rose to prominence and international renown. From here Buddhism spread to Tibet, Nepal, Bhutan, Myanmar, and Indonesia. Dipamkara Srijñana (ca. 980–1052), abbot of the Vikramashila monastery, reformed Buddhism in Tibet and laid the foundations for the Kadampa tradition. Tilopa (988–1069) founded the Tibetan Kagyu tradition. The University of Nalanda was destroyed by fire in 1193 by the Turkish-Afghan general Bhaktiyar Khalji. A few years later it was totally abandoned.

The Pala Army consisted of the same four divisions (infantry, cavalry, elephants, and chariots) as earlier Indian armies. Likewise, a *senapati*, or general, stood at its head. Cavalry was recruited mainly from tribes from the north and the Himalayas and from Rajput groups. Horses could not be bred locally because of the high humidity and temperature of the climate of Bengal, Bihar, and Bangladesh. The cavalry forces often had their own commander.

The names of Pala kings all end in *-pala*, literally “protector.” Gopala, for instance, means “Protector of Cattle,” Dharmapala means “Protector of the Law,” and Devapala means “Protector of God(s).” The ending *-pala* is not restricted to Bengal or to royal dynasties but is a rather common ending to names in northern India.

■ Introduction: Indian Influences in Southeast Asia

Indianization” is the term used to describe Indian influence on the development of Southeast Asian societies. This influence involved a number of areas including the concept of royalty (court customs, installation, pageantry), administration and law, writing systems, linguistic borrowing, the epics *Ramayana* and *Mahabharata*, and literary works on subjects such as philosophy, astrology, medicine, and the arts. That there was such Indian influence cannot be denied; from the temple ruins at Angkor in Cambodia and Borobudur on the island of Java to the linguistic remnants in the Philippines, the evidence is plentiful. However, certain issues are not as clear. For example, the explanations for how and why Indian influence came to Southeast Asia depend on the question of initiative.

The connection between South Asia and Southeast Asia was quite strong. Paul Mus argued that India and Southeast Asia had a “common primordial substratum of belief.” However, with the exception of northern Vietnam, Chinese cultural influence was negligible. The Chinese viewed Southeast Asians as barbarians or non-Chinese and therefore not worthy of assimilating Chinese culture. China did keep ongoing economic and political bonds with various political entities in Southeast Asia. This was to maintain a buffer on its periphery and to keep the region weak and divided. As long as Southeast Asian kingdoms (as the Chinese designated them) paid tribute, China was content.

Most of what is known as Indian influence was found among those in positions of leadership and their courts. The political systems—the Chinese called them kingdoms, modern scholars refer to them as states, and O. W. Wolters used the Sanskrit term *mandala*, meaning circle of a king—were centers of spiritual authority and political power, which were constantly shifting.

Southeast Asians believed that certain individuals were superior to others due to the soul stuff they possessed. One’s accomplishments were proof of his spiritual superiority. Rather than establishing or developing political institutions, these leaders would initiate religious cultic systems that both reinforced their spiritual power and superiority as well as allowed their followers to share in or draw from that power. Hinduism provided both the deities and the ceremonies to affirm the royalty of a given leader. Buddhism provided legitimacy by means of promised blessings and curses.

As a result, the initiative regarding Indian influence rested with Southeast Asian leaders who saw Indian culture and religion as tools to be appropriated to enhance and solidify their political status. That Southeast Asian leaders took the initiative is confirmed by the unevenness of Indian influence and the changes made to conform to local situations.

With this in mind, the following scenario is likely what happened. Indian traders, passing through the region on their way to China, came

THE MARRIAGE OF KUANDINYA AND SOMA

The story of Kaundinya is the founding myth of Funan, the earliest known kingdom in Southeast Asia, located in southern Cambodia. The story is associated with other kingdoms in the region as well. At least two versions of the story of Kaundinya have been recorded, one that emphasizes Indian agency and another that emphasizes Southeast Asian initiative.

According to the version that attributes the initiative to Indians, an Indian Brahmin, Kaundinya, is said to have received instructions in a dream and followed them, getting a magic bow from a temple and then leaving on a merchant ship. Upon reaching Funan he defeated Soma, the daughter of the king of the nagas. He then married her and began the royal line of Funan. This version of the legend indicates a double legitimacy of the royal family, one in its Indian roots (Kaundinya) and indigenous mythology (daughter of the nagas).

The version recorded by the Chinese in the third century CE tells of a local princess, called Lin-yeh by the Chinese, who led an attack on a passing ship; some say that it was a Southeast Asian vessel, while others say that its origin was unknown. The ship's crew and passengers successfully repelled the attack. When they landed, one of the passengers, an Indian named Kaundinya, drank of the water of the land and subsequently married Soma. This version points to Southeast Asian initiative, which originally was more aggressive and violent and was unsuccessful. The marriage of Kaundinya and Soma represents an intermingling of Indian and Southeast Asian cultures.

—Damon Woods

into contact with the local population and probably sought to deal with the local leader or authority. In the course of their dealings with Indian traders, local leaders learned from the traders of religious and political systems in India. Taking the initiative, these Southeast Asian leaders sought the assistance of educated and priest caste Indians (Brahmins), who brought various aspects of Indian culture back to Southeast Asia to reinforce the positions of local leaders. (Of the castes, the Brahmins alone possessed the knowledge brought to Southeast Asia. Thus, while the merchants—belonging to the Vaisya

caste—were the initial contacts, they could not have brought the knowledge that Southeast Asian leaders wanted. As a result, some speak of Hinduization rather than Indianization. This is too narrow a description, as Buddhism and other aspects of Indian culture were brought to Southeast Asia.) These might have included different aspects of the pageantry and ceremonies involved with the installing of a new leader, political administrative systems, the borrowing of Sanskrit terms to describe new realities in Southeast Asian politics, writings systems for the purpose of keeping records, the epics that would be rewritten with the leader as the heroic figure, any kind of scholarship, and the visual arts for the building of monuments and temples.

Indian influence came to the region in a process that covered more than a millennium as political leaders and their systems came and went. Each leader would select those aspects of Indian culture, including Hinduism or Buddhism, that best suited his situation and rule. For example, in Funan, the earliest kingdom in Southeast Asia, Indian vocabulary was used in conducting affairs of state, but Indian cosmology and statecraft did not have real significance. Indian-styled names and titles were popular in the kingdoms of Angkor and Champa. One finds *varman* added as a suffix to royal names such as Indravarman, Rajendravarman and Jayavarman. Those following Hinduism had a choice of various deities, but Siva came to dominate. Yet even when a particular god, cult, or religion was chosen, there would be a blending of various beliefs. For example, Sanjaya, one of the early leaders of Sailendra, a political system on Java in the eighth century, followed the Siva cult, or Saivism as it is known. His successors were Indra, Visnu, and Indra II. But in spite of the fact that they had names of Hindu gods, they were all Buddhists and built Borobudur, the great Buddhist monument in central Java. The temple complex at Angkor in Cambodia has temples to Siva and Visnu as well as Buddhist temples. The title and concept of bodhisattva (Buddha in the becoming) was appropriated by some kings who used Buddhism as their state religion.

This indicates that Indian culture was not adopted wholesale and uncritically. What one finds is a process described by scholars as do-

mestication, localization, indigenization, and local genius. That is, Southeast Asians picked and chose those parts of Indian culture that best suited them. This selective borrowing is seen in many areas, but the place of women in Southeast Asian society is perhaps the best example. It is important to remember that Southeast Asians borrowed cultural forms while retaining indigenous thinking. Thus, Justin van Leur wrote of the “thin, flaking glaze” to describe the place of Indian cultural influence in the region. One can make the distinction between core values, which were Southeast Asian, and surface values, which were borrowed from other cultures.

Southeast Asian Mainland States

From the early Christian era, several mainland Southeast Asian states developed in the silt-rich deltas of present-day Cambodia, Vietnam, and Myanmar, where the fertile soil contributed to agricultural prosperity and the proximity to the sea strengthened the growth of commerce. The origins of these early states, their exact locations, the names of the rulers, and the dates they ruled are still debated by scholars. However, there is a general consensus that these early states were influenced by Indian culture and sent embassies to Chinese courts during this period.

Funan, the pre-Khmer kingdom established in present-day Cambodia, was the first great power, flourishing from the first century CE to the sixth century CE. Its ruler claimed divine status with the title “Kings of the Mountain.” According to the Chinese record, an Indian Brahman named Kaundinya, guided by a dream, came to Funan, where he married the queen, Soma, daughter of the king of the Nagas (Snake),

and founded the dynasty. This legend and the title were adopted by the Khmers and other Southeast Asian states. Its capital city Vyadhapura, near present-day Phnom Penh, was 120 miles from the sea; its port Oc Eo was the center of foreign trade.

In the third century the crown was transferred to a new dynasty of indigenous lineage, beginning with Fan Shih-man. He promoted foreign trade and with a strong fleet controlled the area from Annam in the east to the Bay of Bengal in the west and south to Malay Peninsula. A second Kaundinya dynasty ruled in the fifth century, during which the laws were modified to strengthen Indian influence. Sanskrit was the court language, and Hinduism was established in Funan. But Buddhism also flourished after the fifth century. The Funan kingdom retained power until the death of King Jayavarman in 513. It disintegrated in the middle of the sixth century and was finally overthrown by Chenla, one of its vassal states established by the Khmers.

The Khmer conquerors inherited Funan culture and its dynastic traditions. Isanvarman I (611–635) built the first Khmer capital, Isanapura (present-day Sambor Prei Kuk) in central Cambodia. His authority stretched over Cambodia, South Vietnam, central Thailand, and the upper Malay Peninsula. Before the end of the seventh century, Chenla split into Upper (Land) Chenla, and Lower (Water) Chenla, weakening its rule. In 790 the Sailendra rulers of Java invaded Chenla and killed its king, bringing the pre-Angkor Khmer period to an end.

King Jayavarman II (877–889), who expelled the Sailendras and declared himself *chakravartin* (ruler of the universe), laid the foundation of the great Khmer kingdom of Angkor. The greatness of the Khmer civilization was established through his successors' territorial conquests over the next five centuries, along with the architectural splendor of Angkor and its environs. Indravarman I (877–889) was known for his irrigation works and his temple Preah Ko. Meanwhile, his son Yasovarman I (889–915) built the first city of Angkor, Yasodharapura, along with the massive East Baray water reservoir. Jayavarman V (968–1001), under whom the country experienced remarkable peace and cultural prosperity, founded a new capital, Jayenanagari,

A Champa temple at Mison, present-day Vietnam. Throughout the medieval period, the Cham kingdom contested central and southern Vietnam with the Vietnamese. The Vietnamese finally conquered the last Cham state in the sixteenth century. (Ina Van Hateren)

and many temples including Banteay Srei, the most beautiful and artistic of Angkor. Suryavarman I (1002–1005) expanded Angkor civilization to present-day Lopburi in Thailand and Kra Isthmus. His significant accomplishments included the great West Baray reservoir. Jayavarman VII (1181–1219) founded Angkor Thom and the Bayon. The Khmer civilization reached its apex during his reign, but ambitious expansion and wars also led to its destruction.

During the second century CE near the present-day Hue in Vietnam, a local leader named Kiu-lien established a kingdom named Champa

(Lin-Yi) after overthrowing the Chinese authority. Champa, covering the present-day central Vietnam provinces, left archaeological residues of Indian influence. Around 400, King Bhavavarman founded the first temple of the Hindu god Siva in the Mison area. China invaded Champa in 605 during the reign of Sambhuvarman. In 653 Champa extended its rule to the south of the modern Cap Verella under King Vikrantavarman, the grandson of King Isanavarman of Chenla. King Indravarman II (854–893) established a new capital, Indrapura, in Quang Nam Province and built a great Mahayana Buddhist monastery at Dong-duong. For more than 1,000 years Champa was capable of defending itself from the attacks of the Chinese, Vietnamese, and Khmer but was finally conquered by the Vietnamese.

The Mons, ethnically related to the Khmers, also developed a state with its capital at Thaton in Myanmar from the early Christian era. In the Menam Valley, another Mon state called Dvaravati, which was first established at Lopburi with a second capital at Haripunjaya, rose to power, controlling part of Tenasserim in the seventh century. The Mon capital of Hamsavati, now Pago, was founded in 825. During the tenth and eleventh centuries, Thaton, Dvaravati, and Haripunjaya were joined as a Mon confederacy called Ramanyadesa. Adopting Indian traditions of kingship, Vishnu worship, Buddhism, and Sanskrit and Pali writing systems, the Mons developed a high civilization that was later transmitted to the Myanmar and the Thai peoples.

The Pyus, a Tibeto-Burman people, developed a state that flourished from the sixth to the ninth centuries. Their capital city, Srikshetra, was established around 638 in present-day Hmawza near Pyay, at the head of the Irrawaddy Delta. The old palace site, consisting of a massive wall with impressive internal and external moats and gigantic Buddhist images and temples, exhibited the greatness of the Pyu kingdom. The stone sculptures of Vishnu and the bronze statuettes of Avalokitesvara found in Srikshetra evince Indian Hindu influence. However, images of Mahayanist bodhisattva reveal the existence of Mahayana Buddhism, while Pali inscriptions witness the adoption of Theravada Buddhism. Chinese records note that Srikshetra was a center of Theravada Buddhism in the seventh century. From

673 to 718 a Vikrama dynasty, Suryavikrama, Harivikrama, and Sihavikrama, ruled the country. The Pyu challenged the Mon's control of lower Myanmar; this struggle lasted throughout most of the eighth century. Pyu claimed suzerainty over 18 states, including the Mon state with an important trading port, Mo-ti-po. Invaded by the Tai state of Nanchao in present-day China, the Pyu kingdom collapsed in the ninth century.

Island Southeast Asia— Srivijaya and Sailendra

Funan, the earliest known kingdom in Southeast Asia, dominated trade during the first half of the first millennium CE. This was due to its location in southern Cambodia. Traders from the Middle East and India sailed to the Isthmus of Kra, crossed it, and then sailed across the Gulf of Siam to Funan. From there they either would sail around southern Vietnam or across Cambodia to the South China Sea by means of a series of canals built for that purpose and the Mekong River. When the Malacca Straits replaced the Isthmus of Kra route between India and China, this led not only to the decline of Funan as an economic center but also to the emergence of a series of small ports as political entities in the region. These political systems emerged as a result, in part, of the growth of trade in the region. Initially, Southeast Asian ports provided facilities—housing, supplies, and places for repairs—for those passing through. In time, these ports became places where goods that could serve as substitute products for foreign products could be traded (e.g., pine resin for frankincense and benzoin or gum benjamin for myrrh). Later, products unique to Southeast Asia were traded in these ports. These products included camphor, sandalwood, nutmeg, and cloves.

In the seventh century one of these Sumatran ports, Srivijaya, emerged as a dominant political and economic center. The capital of Srivijaya was on the site of modern Palembang, which is located about 80 miles inland on the Musi River on the northern side and the eastern end of Sumatra. Its location at the southern mouth of the Malacca Straits made it an ideal place to trade, resupply, repair ships, and wait for the winds to shift. While other ports also had locations that enabled them to provide those services needed by traveling traders, the ruler of Palembang became the dominant figure in the region. Srivijaya involved three parts: the core area around the capital, Palembang; the land along the Musi River; and other ports and their surrounding areas. The areas outside Palembang were controlled indirectly by means of alliances with local leaders. Srivijaya was able to dominate commerce passing through Southeast Asia by getting rid of competition, gaining control of the seas by putting down piracy, and having a trading center.

However, its location is not sufficient to explain the ascendance of Srivijaya. Other ports had locations with similar advantages to Palembang. In addition, products such as camphor and sandalwood were not grown in the area around Palembang. The spices that brought traders to the region only grew in the Moluccas, far to the east. The area around the Musi River did provide a better agricultural base than any of the other ports. Factors responsible for Srivijaya's ascendancy, beyond Palembang's strategic location, included the superior use of military force used to subjugate surrounding systems, the connection of Palembang's leader to the water spirits (*nagas*), and Buddhism, which found in Palembang a ceremonial center. Above all, the leadership in Palembang was willing to share the wealth generated by the interaction with traders. The political structure of Srivijaya, at least in terms of titles, imported or borrowed from Indian systems. The royal administration, located in Palembang, had Sanskrit titles: for example, *baji* (king), *dandanayaka* (judges), *nayaka* (revenue collectors), and *pratyaya* (managers of royal property).

A hundred years before Srivijaya emerged as a dominant commercial political system, there

> CURSES!

As Srivijaya and all other Southeast Asian political systems in the first millennium CE were supported by religious structures and systems, the promise of curses as well as blessings were used by leaders to keep their subjects in line. In Srivijaya, the king (*haji*) was seen as a patron of both Buddhism and the local belief in the *nagas*, spirits who lived in water and were the keepers of life and energy in water, the primary means of transportation in trade. According to the *Telaga Batu* inscription, dated circa 686, the subjects of the king were to take an oath. Magical imprecations or curses from both the Buddhist system and the indigenous beliefs in the *nagas* were threatened. From the Buddhist system, a curse was pronounced against those who were guilty of love of self, anger, and greed, violations of Buddhist prohibitions. Threats from local beliefs included one's being swallowed by a big river. On the other hand, those who followed the king were promised a prosperous future. Among the promises were growth and prosperity, arriving at a perfect state, the secret formula for final liberation, and the eternal tranquility of Nirvana.

—Damon Woods

were kingdoms based on rice production developing across the Sunda Straits on the island of Java. Location was critical. The soil of central Java was fertile due to volcanic activity and provided the basis of significant rice production. One kingdom, known as Sailendra, located on the Kedu Plain on central Java emerged as a dominant power in the ninth century. While Sailendra had ports on Java, that was not the focus of their energies. Produce, principally rice, beans, salt, and dyes, was the basis of its wealth. However, there were at least four levels or layers of merchants between them and the international market.

The political development of Sailendra and other rice-producing states followed a similar pattern. The use of indigenous terminology demonstrates that the development was organic and not artificial or adapted from Indian models. The term *wanua* referred to a cluster of villages populated by *anak wanua*, children of the *wanua*. These were governed by *tuba* (elders)

and *rama* (fathers on the council). The most important official was known as the *bulair*, the head of the local water board. These *wanua* shared a common market, *pken*, and a collection of *wanua* made up a *watek*. The official in charge of irrigation for the *watek* was the *rakrayan*. A powerful *rakrayan* in charge of a prospering *watek* could bring other *rakrayan* and their *wateks* into an alliance under his authority. At this point, Indian influence made itself felt. The next title that one could take was *raja*, with the possibility of becoming a *maharaja*. Indian priests would be brought in to legitimize his rule with elaborate ceremonies.

In the last two centuries of the first millennium, temples were built on the mountainsides and plains of Java. A Hindu temple complex on the Dieng Plateau marked the beginning of this output of religious structures, and another Hindu complex at Prambanan marked the end of this boom of temple building. In between, Sailendra built the Buddhist monument Borobudur, which became a pilgrimage center.

Sailendra lasted a little more than a century, being pushed aside by another kingdom. The Sailendra prince fled to Srivijaya, where he ascended the throne. Srivijaya and Sailendra were able to coexist peacefully for several reasons. First, Buddhism was the dominant religion in both, providing the symbolic source of authority. Both kingdoms were pilgrimage centers and known for Buddhist scholarship. Sailendra's leaders built the great Buddhist monument, while Palembang was the location of an international community of Buddhist monks, at one point numbering around 1,000 monks. Second, each kingdom had different basis for existing—Srivijaya for trade and Sailendra for rice production—and thus there was a minimal amount of direct competition.

However, each kingdom was pushed aside and replaced in importance by others. As the second millennium began, Majapahit, a Hindu kingdom, emerged on Java, embracing both commercial and agrarian aspects.

The Philippines to 1000 CE

Chinese records, archaeological finds, and reconstructions based on the available evidence have been essential to learning about Philippine societies in the first millennium CE. In the mid-1970s an archaeological team discovered the remains of two seagoing vessels near Butuan City

in Mindanao. Using carbon 14 dating, one was found to come from the early fourth century CE and the other from the mid-thirteenth century CE. These finds would indicate that the people of the archipelago did travel to other parts of Asia, no doubt to trade. Descriptions of vessels from Chinese texts of the third century CE match the one found in Butuan. One historian stated that "by the third century A.D. the islanders of the Philippines were sailing 800 miles and more across the open sea to Funan" (one of the earliest kingdoms of Southeast Asia, located in southern Cambodia). He based his statement on both the artifacts excavated at Oc-Eo (a Funanese port) and the Kang Tai report that the peoples of Southeast Asia brought their goods to Funan. Among the products brought were those found in the Philippines: pearls and gold.

➤ LAGUNA COPPERPLATE INSCRIPTION

Until recently, the sources of information for reconstructing Philippine societies prior to the Spanish intrusion were limited. A discovery in the 1980s has provided significant information about the state of some societies in the Philippines in the ninth century. Known as the Laguna Copperplate Inscription, this document was accidentally discovered as the result of dredging for sand and gravel in the provinces of Laguna. The document is not only the earliest document discovered in the Philippines, it is also the only pre-Spanish document that has been discovered thus far. Written on a thin copper plate, it was dated using the Sanskrit calendar and translates to April 21, 900. A *sud-dhapattra*, a legal document of the cancellation of a debt, it states that a debt of gold (865 grams) owed by a certain Namwaran has been cancelled. Given to his daughter, Angkatan, the document was written in a language that contained elements of Old Javanese, Old Tagalog, and Sanskrit. Sanskrit was used for technical terms, including the dating of the document and the political titles of the individuals involved. Among the fascinating aspects of this document is the chain of command that is described. The authority to cancel the debt was exercised by a local ruler and witnessed by local rulers, who were under the authority of the ruler of Dewata (in Mindanao), who was under the authority of the ruler of Medang (in Java). Thus,

The Laguna Copperplate Inscription, the oldest known document found in the Philippines, dates from the ninth century. Little is known of the Philippine kingdoms that existed before the Spanish conquest in the sixteenth century. The Spanish effectively destroyed the collective memory of these kingdoms. (Santos, Hector. "The Laguna Copperplate Inscription" in A Philippine Leaf at <http://www.bibingka.com/dahon/lci/lci.htm>. US, October 26, 1996)

there was a political connection that ran from Java all the way to the region around Manila Bay. This radically challenges the notion that the Philippines were isolated from the rest of Southeast Asia. The Laguna Copperplate Inscription shows that at least communities in the Manila Bay area were active and interactive parts of the region.

—Damon Woods

The work done by archaeologists has pointed to organized and widespread trade, first between the Chinese and coastal inhabitants and then between the people of the coast and the people of the interior. The presence of trade porcelain throughout the archipelago, in the lowlands and mountains, can be seen as evidence that such porcelain was first brought by Chinese traders and traded with coastal communities. The products traded for the porcelain included those from the sea (pearls, coral, tortoise shell) and those from the interior (beeswax, sandalwood, rattan). Thus, the coastal communities must have had working agreements with people of the interior, and in this way Chinese trade porcelain made its way into even the most remote areas of the islands. However, there appears to have been contact with Indian traders that predate contact with the Chinese. Both metal and glass artifacts, believed to have originated in India, have been found.

Unfortunately, all of this does not tell us much about the local inhabitants or their customs. Beyond political fragmentation, evidenced in the scattered communities unearthed by archaeologists, the rest is guesswork based on existing evidence. New discoveries may shed more light. One such discovery in the 1980s has transformed existing views of the level of political, economic, and cultural development of pre-Spanish Philippines.

■ Introduction: The Radiance of the Tang Dynasty in Southeast Asia

The Tang dynasty (618–907) was known throughout Asia for its brilliant culture and its grandeur. It has rightly been referred to as China's golden age. The Tang reached their height in the eighth century, and their power attracted the interest of neighboring states that imitated Chinese customs. During the Tang dynasty, China also served as a cultural conduit, absorbing and passing on ideas from one region to another.

China's lucrative trade and rich port cities attracted many visitors. Foreign merchants traded for Chinese goods such as silk but often took away much more, including Chinese customs and culture. Students from neighboring countries came to China to learn from Buddhist and Confucian masters. In 640 over 8,000 Koreans, mostly students, lived in China's capital of Chang'an. Embassies from surrounding states came to China's capitals and were exposed to Chinese culture, technology, philosophy, litera-

ture, administrative systems, land systems, Buddhism, art, architecture, and medicine. China's government and administration became models for several emerging nation-states in the region.

Chinese citizens also traveled abroad, carrying their culture and customs with them. Tang princesses traveled to distant lands as part of the time-honored practice of diplomatic marriage. These women, real princesses or created by imperial command, were married to the royalty of other kingdoms, creating diplomatic connections with peoples such as the Uighurs, Turkic khans, and Tibetans. The women traveled to their new homes with pomp and splendor befitting representatives of Asia's superpower status, and their presence opened the way for increased interaction with the Chinese.

King Songtsān Gampo of Tibet was so attracted by the wealth and culture of the Tang that he sent envoys to the capital of Chang'an on several occasions requesting a marriage alliance.

TANG CHINA AND EAST ASIA, 618-907

In 640 his wish was granted. His wife, the Tang princess Wen Cheng (Tibetan: Mung-chang Kung-co) helped promote friendship between Tibet and China and helped spread Tang culture. She is credited, at least in folklore, with teaching the Tibetans spinning and weaving. Chinese engineers and doctors in her entourage passed on their knowledge, including how to construct water-powered mills for grain, and the king used the Chinese system as a model when he set up his military and administration. Perhaps most importantly for the history of Tibet, Wen Cheng brought her statue of Sakymuni. Under her influence the king converted to Buddhism.

Like Tibet, surrounding countries looked to China for religious inspiration. As Buddhism lost importance in India, China became the primary source of Buddhist teachings. The Chinese sect

of Chan Buddhism, begun in the eighth century, spread to Japan, where it was known as Zen, and to Korea. Devotees from around Asia traveled to China to visit its many shrines and temples and to study with Chinese masters.

Although Chinese influence in Japan began well before the Tang period, it reached its height during the Tang. Every aspect of Japanese life was affected, and gradually Japan embraced Chinese political and administrative methods, language, writing, literature, technology, and religion. Japan based its Taiho Code, published in 701, on Tang code. The cities of Heijo (Nara) and Heian (Kyoto) were modeled after Chang'an, with straight wide streets laid out in a grid pattern. Court education consisted primarily of reading Chinese texts and reading and writing Chinese poetry and prose. Chinese became the

THE JAPANESE MONK ENNIN VISITS CHINA

China's brilliant culture attracted many foreign visitors during the Tang dynasty. Many traveled for religious purposes, visiting China's many shrines and monasteries. In 838 a Japanese monk named Ennin, known in Japan as Jikaku Daishi, sailed to China. For the next nine and a half years he traveled throughout China, writing in his diary what he saw and experienced. It is the first account of Chinese life by a foreign visitor, for Ennin arrived in China more than four centuries before Marco Polo.

Ennin's diary is particularly detailed and provides a lively view of daily life at the end of the Tang dynasty. One of his interesting discussions covers the imperial prohibition on the sale of iron:

"On the seventh day of the eleventh moon, Chen-shun, a monk of the Kai-yuan-si, privately sold broken pots to a merchant to the amount of ten pounds weight. When the merchant went out with his iron, he ran into some police inspectors at the monastery gate and was arrested and brought back. The five inspectors came and said, 'Recently the Minister of State has prohibited [the use of] iron, and one is not allowed to sell or buy it. How then is it that you have sold some?' Chen-shun replied that he did not know that its sale was prohibited. Then the officer in charge and Chen-shun prepared documents asking for a decision, and the officials pardoned him. Thus we learned that within the jurisdiction of Yang-chou [Hangzhou] the sale or purchase of iron is not permitted."

—Rebecca Wendelken

Edwin O. Reischauer, *Ennin's Travels in T'ang China* (New York: Roland, 1995), 7–8.

language of law, philosophy, history, and religion up until the nineteenth century. All Buddhist sects in today's Japan are rooted in Chinese Buddhism from the Tang dynasty.

Despite all this, Japan did not adopt Chinese ideas completely. During its Nara (710–784) and Heian (794–1068) periods, Japan began to selectively choose elements of Chinese culture for adoption. Those selections were then adapted to Japanese society to create a distinct culture of their own. Japan embraced Chan Buddhism but continued to practice Shinto. Court ranks and

rewards were based on Chinese models, but the interior workings of the court were based on birth and not on the Chinese examination system. Likewise, the Japanese did not adopt the practice of using eunuchs at court.

Korea's connections with China are even older than Japan's, and many Chinese lived in the kingdoms of Paekche and Koguryo. China conquered a good deal of Korea before the eighth century, when the native kingdom of Silla rose to power. There were close contacts between Silla and the Tang in the last half of the seventh century. They exchanged diplomatic embassies, and Korean students and monks traveled to China to study and worship. Koreans were found in the areas along the Chinese coast. The impact of Tang fashion on Korea can be seen in Korean traditional ceremonial wear. At first the Silla tried to drive out the Chinese but soon realized that they did not have enough military force. Instead, they used diplomacy. China removed itself from the Korean Peninsula, and the Silla king recognized the emperor of China as his overlord. The kingdom of Silla became a vassal of China, and its envoys traveled with gifts to the Chinese court. There they showed their submission by kowtowing to the emperor. But the relationship was very beneficial for the Koreans. They received far more in gifts from the Chinese than they paid in tribute. The Silla built a new capital modeled on Chang'an, and the elite began to read and practice the teachings of Confucius. Like Japan, Chan Buddhism also spread to Korea.

Vietnam had a far more contentious relationship with China. Tang armies moving into Vietnam met strong resistance, but China soon had control of the Viet's cities and towns. Despite Viet resentment and resistance, China embarked on a plan to absorb the Viet people into China. The Viet people adopted many aspects of Chinese culture including methods of agriculture, administrative structures and educational models, and even Confucianism and Buddhism. As the Tang dynasty was collapsing, Vietnam won its freedom and succeeded in resisting incursions from China during subsequent dynasties.

The impact of the Tang dynasty on its neighbors is undeniable. Its vibrant art and culture and its governmental policies and structure provided a model for the developing countries along

its periphery as well as those as far away as Persia and Byzantium.

Political History of the Tang Dynasty before the An Lushan Rebellion

The Tang dynasty (618–906) was a golden age in China's history and stands out as one of the most prosperous empires in the history of the world. On the collapse of the Sui dynasty in 617, Li Yuan swiftly seized the two Sui capitals. In 618, he proclaimed the founding of the Tang dynasty with the capital at Chang'an ("perpetual peace").

Its political structure was based on that of Han as well as the Northern and Southern dynasties of the Period of Division (304–589 CE). With the innovations of the first half of Tang, it became a fully matured system of checks and balances that was looked upon as a model in later centuries. Tang was also the most cosmopolitan period of Chinese history, open to influences coming from far and wide.

Known by his posthumous title of Gaozu, Li Yuan (r. 618–626) devoted himself to the restoration of peace and order. He reappointed Sui administrators and rewarded anti-Sui rebels with positions of power. A comprehensive legal code laid a foundation for later ages. The equal-field system, established in the fifth century, granted land to adult males, who in turn were to pay taxes and labor service. He continued the Sui militia system of conscripting soldiers for defense, and like his Sui predecessors, Gaozu promoted Confucianism, Daoism, and Buddhism to consolidate cultural unity.

In Gaozu's reign, the civil service examinations, a system of recruiting candidates for the bureaucracy that had its origins in the Han dynasty, were reestablished. The examination system was a unique feature of the Chinese imperial administration, which gave it strength and durability. The Tang further developed the examination system, replacing an aristocratic government with meritocracy, and it lasted until 1905.

The second emperor, Taizong (r. 626–649), was a man of broad vision and boundless ambition. He came to the throne by assassinating the crown prince and forcing his father to abdicate. Most remarkable in his reign was the improvement of the bureaucratic system of three departments that Gaozu inherited from the Sui. Under this system, the Department of the Secretariat drafted edicts, the Chancellery reviewed them, and the Department of State Affairs implemented them, bringing about an effective bureaucratic system of checks and balances to support the monarchy.

The Li royalty belonged to a long lineage of mixed Chinese and non-Chinese blood tracing back to the Period of Division. The nomadic horse-riding tradition contributed not only to the military vigor of Taizong and his siblings but also to Taizong's vision of a universal empire in which the ruler would be both the Chinese Son of Heaven and the khan over the nomadic peoples. While forming a marriage alliance to appease the newly rising Tibetan kingdom, Taizong initially concentrated his forces against the Turks, seeking to establish control over the Western Regions as well as to extend Chinese rule over North Korea. After the conquest of the Eastern Turks in 630, he assumed the title "Heavenly Khan." His vision made the Tang capital a cosmopolitan city, attracting people from all over Asia including Nestorian missionaries.

Although Taizong failed in his Korean campaign, the next emperor, Gaozong (r. 649–683), succeeded. By 660, Tang had established its administration far beyond its previous limits. Gaozong, however, is mostly known for his empress, Wu Zetian. In 660 when he suffered a stroke, Empress Wu became a joint ruler with him behind the scenes and continued to hold the power after his death. In 690, she proclaimed herself the emperor of the Zhou dynasty and was only forced to abdicate shortly before her death in 705. The reign of Gaozong and Empress Wu continued efforts at improving government and perfecting the legal code. Since Empress Wu's rule as a woman was challenged by both internal revolts and by a revived Turk empire, she had to make great efforts to secure her power, but she never neglected government duties. Externally, when the Tang expansion became overextended,

► EMPRESS WU

Empress Wu ruled Tang China for nearly half a century (660–705) in its time of glory and power. A skilled administrator and military planner, she promoted peace and prosperity within China and presided over a significant expansion of Chinese power into central Asia. Despite her vilification by male Chinese historians, she is considered by some as a great ruler in history.

Wu Zetian came from a prominent family. Her career began as a low-ranking concubine of Taizong. After his death, she duly entered a Buddhist convent, but through successful intrigues she returned to the palace, became Gaozong's favorite concubine, and in 655 made Gaozong dismiss the empress and elevate herself into that position.

Wu's rise was due to her clear understanding of the intricacies of politics and her superb ability at manipulating factional struggles to her advantage.

While she exercised terror, she elevated the widely practiced Buddhism as a state religion. Though self-serving, her assuming a public role in performing court rituals, extending the mourning period for a mother to that of a father, and having literary works of exemplary women compiled could be regarded as protofeminist.

—Yihong Pan

Eighth-century Chinese empress Wu Zetian, from an eighteenth-century album of Chinese emperors. Empress Wu was one of the most effective rulers of the Tang dynasty. (The British Library)

Empress Wu from 670 turned to a policy with more emphasis on defense.

Fierce power struggles went on for seven years after the death of Empress Wu until 712, when Xuanzong (r. 712–756) emerged victorious. An immensely capable ruler, he brought Tang to its peak. (French historians sometimes compare Xuanzong to Louis XIV.) Xuanzong's reign saw a restoration in the coordination of the Three Departments. A major taxation reform increased revenue, enabling Xuanzong to switch from frontier defense to expansion westward until the Chinese Army was defeated by the expanding Abbasid Caliphate in central Asia at the Battle of Talas in 751. Xuanzong was a great patron of the arts, and his reign is remembered as a golden age of poetry. While diffusing Chinese culture eastward to Korea and Japan and westward to central Asia, under the Tang dynasty China was open to outside influences, receiving Zoroastrianism, Manichaeism, and Islam and embracing various foreign cultural elements.

Yet crisis was looming. Tensions were deepening among the central, regional, and frontier governments and between the outer court of the regular bureaucracy and the inner court of the powerful relatives of the royal family.

Xuanzong needed to be able to maintain a delicate balance between these rival forces, but in his later years he withdrew from these complicated politics into the world of his beautiful, artistic Yang Yuhuan, known by her title *guifei* ("honored consort"). In 755, An Lushan, a military governor on the northeastern frontier of mixed Turkish and Sogdian origin, rebelled in the name of opposing the dictatorial chief minister, Yang Guozhong, cousin of Yang Yuhuan. Although Tang survived this disastrous rebellion that lasted until 763, it never regained its earlier verve.

Late Tang and the Period of Five Dynasties and Ten Kingdoms, 756–960 CE

The Tang dynasty (618–907), one of China's most glorious, flourished for about a century and a half until An Lushan's Rebellion (755–763) fatally weakened it. To restore order, the court was obliged to call in the aid of the Turkic Uighurs, who exacted a high price in tribute.

The An Lushan Rebellion changed Tang drastically. The power of the court decreased vis-à-vis the strong provincial governors. In settling the rebellion, the court had compromised with the rebel forces and appointed their leaders as military commissioners in the territories they occupied in present-day Hebei and parts of Shandong and Henan. Although accepting titles from the court as symbols of legitimacy, these generals governed their territories as independent fiefdoms. In the rest of the country, regional commands formed a new tier of provinces between the central government and the prefectures under military or civil commissioners appointed by the central government but often acting with a good deal of autonomy.

When he came to the throne, Dezong (r. 780–805) was determined to revitalize the central government and carried out reforms assisted by his ministers. He adopted a firm policy toward the semiautonomous provinces, which

only resulted in touching off a series of civil wars. In response, Dezong returned to the laissez-faire policy of his predecessors. His reform of taxation, on the other hand, proved a success. With the collapse of the Equal Field System, the government acknowledged private land ownership and implemented the two-tax system levied on households and on land and payable in cash. This along with the monopoly on salt, tea, and liquor production and distribution increased government revenues. It also enabled the state to derive revenue from all the productive classes, not from the peasantry alone. When Xianzong (r. 805–819) ascended the throne, the young and forceful emperor engaged in a series of confrontations with the semiautonomous provinces. For a while his reign seemed a period of central government resurgence. Yet it was marked by entrenchment of the power of the eunuchs. The emperor was either murdered by eunuchs or died of a drug overdose.

The problem of eunuch influence in court policies was not new. While not a serious issue in the prerebellion period, the power of eunuchs grew steadily in the postrebellion period. The most important contributing factor was the eunuch command of the Palace Armies, which began during the rebellion. Under Dezong, eunuch control of the Palace Armies became permanent. The eunuchs interfered in almost all imperial successions from 819 until the end of the Tang. From the mid-ninth century in their factional struggles within the regular bureaucracy, each side was trying to obtain the support of powerful eunuchs, which further increased the eunuch's power and eroded the government.

Postrebellion Tang had shrunk from its earlier overstretched territory. In its foreign policy, Tang was on the defensive and became more flexible and pragmatic. Taking advantage of the rebellion, the Tibetan kingdom expanded into Chinese territory into present-day Gansu, cutting off the line of communication between Tang and the Western regions (present-day Xinjiang), thus effectively ending Tang influence there. From their occupied territory to the west of Tang China, the Tibetans engaged in frequent incursions. In 763 they even briefly occupied the Tang capital and attempted to establish a new puppet emperor.

► THE CONCUBINE AND THE REBEL—YANG GUIFEI AND AN LUSHAN

In the summer of 756 in the chaos of the An Lushan Rebellion, Xuanzong had to flee the capital accompanied by a small number of troops, his favorite consort Yang Guifei, and her family members. Soon, however, his troops demanded the death of Yang Guifei, accusing her of distracting the emperor to the neglect of state affairs. Xuanzong complied. In Chinese popular tradition, the tragic end of Xuanzong's reign was featured by An Lushan, the barbarian rebel, and Yang Guifei, who epitomized seductive femininity. All sorts of scandalous stories circulated about them in later fictions and dramas, implying illicit relations between them such as that An had free access to the harem and that he shared meals with her and sometimes spent the entire night in the harem. It is impossible to know the truth. The *Old Tang History* itself indicates a close relationship. An asked to be the adopted son of Yang, apparently a move to secure the trust and favor of Yang and the emperor. When paying respect to his adoptive parents, An Lushan bowed to Yang Guifei first. When the emperor was surprised, An offered this explanation: "The barbarians show respect to the mother first and the father second." On the celebration of An's 48th birthday in 751, the mother gave An a ceremony of washing her baby when An was dressed in a diaper. Such a bazaar behavior as an evidence of the court's moral declining further puts the blame on the barbarian An Lushan and the woman Yang for the disasters of the nation.

Translation by Yihong Pan.

In coping with this most formidable enemy, the Tang usually opted for a peaceful policy. They concluded five peace treaties with Tibet while also maintaining an alliance with the Uighur empire against Tibet. The alliance was maintained through seven marriage contracts of Tang princesses with the Uighur rulers as well as through the regular horse-silk trade, with

China purchasing Uighur horses in exchange for silk. Although uneasy and costly, the alliance was successful in maintaining some balance of power in the complicated regional geopolitics. The Tang also managed to win over the Nanzhao kingdom in the southwest from a previous pro-Tibetan stance, preventing Tibet from moving farther into Tang's southwest.

As the court readjusted China's status in regional geopolitics, among the intellectual elite there was a reassessment of what constituted Chinese culture. A famous example is Han Yu's memorial to the court against Buddhist rituals. This was not so much based on a rejection of Buddhist ideas as on a deep concern that Confucianism and China's national spirit were losing ground. In 842–845 Wuzong (r. 840–846) carried out a great proscription of Buddhism and other foreign religions. While the proscription was primarily concerned with the economic drain of religious institutions, such hostility also resulted from Tang's sense of insecurity in international affairs.

Although the brilliance of Tang as a centralized and expansive power dimmed, postrebellion China witnessed steady and impressive economic development. With people migrating to the south to avoid chaos during the rebellion, economic importance moved from the north to the more fertile and productive south, where the environment was more conducive to agriculture. The introduction of Champa rice from central Vietnam made double cropping possible; tea became a major commodity in trade. As the government abandoned its supervision over the operations of markets, trade increased and markets flourished. Credit institutions grew, and the first paper money in the world, issued by joint merchant houses, appeared in Sichuan around the end of the ninth century. The economic development would continue into an urban and commercial revolution from the tenth century onward.

By the end of the 840s both the Tibetan and Uighur power had collapsed, while Tang was also on a road of fast decline. Waves of rebellion occurred, reaching their height in the rebellion of Huang Chao in 874–884. In 907 General Zhu Wen forced the last Tang emperor to abdicate, thus ending the dynasty and ushering in another

period of division in Chinese history. Known as the Five Dynasties and Ten Kingdoms period, it consisted of a series of short-lived dynasties in the north and regional warlord powers in the south, another period of political disunity in Chinese history but much shorter than before. Half a century later, China was reunited under the Song dynasty in 960.

Tibet, 600–1000 CE

The Tibetan people originated among the nomadic non-Chinese Chiang tribes on China's periphery. The *Old Tibetan Chronicle* states that the empire began with a coup, but the *Chronicle* borders on mythology. The first externally confirmed event of Tibet's history occurred in 608 when a Tibetan ambassador visited China. This diplomatic visit occurred one year before the founding of the first Tibetan dynasty, the Tufan dynasty. Its first ruler, Songtsän Gampo (Srong-brtsan sgam-po) (609–650) moved the capital to Lhasa to remove himself from the areas of deeply entrenched tribalism and to make expansion to the north easier. He promoted agriculture and animal husbandry by reclaiming land and promoting water conservation.

Tibet's military and administrative structure was modeled after China. Educational and diplomatic exchanges between Tibet and China were very important for Tibet's early development. From 634 to 846 the two countries exchanged emissaries about every 13 months on average. To improve communication within his country, Songtsän Gampo promoted the creation of a

script for Tibetan. Although there are several stories about the development of the Tibetan alphabetic script, the actual origin is unknown.

To maintain closer ties with the Tang, Songtsän Gampo sent several envoys to the Chinese capital requesting a marriage alliance. In 640 his wish was finally granted. His wife, the Tang princess Wen Cheng (Mung-chang Kung-co) helped promote friendship between the two countries and also spread Tang culture. Folklore credits her with teaching the Tibetans spinning and weaving. While this may be questionable, she did bring engineers and doctors who taught their skills to the Tibetans. Although her husband is credited with introducing Buddhism to Tibet, it may have been accomplished by Wen Cheng herself. She brought a statue of Sakymuni to Tibet, and according to some sources the king converted under her influence.

Under Songtsän Gampo, Tibet began to expand, conquering and absorbing tribes along China's western border area. The king sent his sister to marry the king of Zhang Zhung, a bordering state. When the marriage was not consummated, the king's sister helped her brother conquer Zhang Zhung, and it too became part of Tibet.

Songtsän Gampo died in 650 and was succeeded by his infant grandson Trimang Löntsän (Khri-mang-slon) (650–677). His reign is chiefly known for the annexation of Azha and later for conquering the important Chinese Silk Roads towns of Kucha, Yanqi, Kashi, and Khotan. This move cut Tang China's communication with their northwest territories and with central Asia. It also interrupted Silk Roads trade and the flow of pilgrims to Buddhist sites in the region. The Khri'bring brothers, who engineered the capture, belonged to the Mgar (Gar) clan. The Mgar often served as regents for infant kings, which gave them a great deal of power. They were eager to expand Tibet's power in order to increase their own.

Tridu Songtsän ('Dus-srong mang-po-rje) (677–704) was born the year of his father's death. His initial reign was orchestrated by his mother Thirmalö Khri-ma-lod, a powerful woman in her own right, and by the Mgar clan. In 692 China regained control of the Tarim basin and the Silk Roads cities, and conflict between the

THE CHINESE VIEW OF THE TIBETANS

Despite the advances in Tibetan civilization, the Chinese held an extremely negative view of them, a view they held about anyone who was not Chinese:

“We are told that the country has a very cold climate, that oats, barley, wheat and buckwheat grow there, and that there are yaks, excellent horses, and dogs, sheep and pigs. The capital is known as Lhasa, where there are city-walls and houses with flat roofs. The king and his nobles live in felt tents which are joined together as one large one. They sleep in unclean places and they never wash or comb their hair. . . . They dress in felt and leather. They like to paint themselves with red ochre. The women plait their hair. They worship the heavens and believe in sorcerers and soothsayers. They do not know the seasons, and their year begins when the barley is ripe. Their games are chess and dice, and for music they have conch-shells and drums. They have no writing for official purposes, and they fix arrangements by means of knotted cords and notched tally-sticks. They make vessels by bending round a piece of wood and fitting in a leather bottom, or they make basins of felt. They knead roasted grain [*tsampa*] into little cups and they fill these with broth or curds and eat it all together. They drink their beer with their cupped hands.

There are hundreds of thousands of men ready to bear arms, and in order to levy troops they used a golden arrow (as insignia of authority). In order to give warning of enemy attacks they use fire and smoke signals. . . . Their armor and helmets are excellent. When they put them on their whole body is covered, with holes just for the eyes. Their bow and their sword never leave them.”

two countries continued. By the end of the seventh century Tridu Songtsän had tired of the control of the Mgar clan. He invited members of the clan to a hunting party, where they were executed. The king then defeated the remaining Khri-bring brother, who committed suicide. This ended the power of the Mgar clan. While the king was bringing down the Mgar clan, his mother served as regent. In 702 China and Tibet agreed to peace, and Tridu Songtsän returned to reorganize his administration. The king died during a military expedition against the Erhai region in 703 during which the Tibetan military suffered heavy losses.

After the king's death, his mother ruled as regent for the child Gyälsugru (704–754). After thwarting an attempt by the king's older brother to usurp the throne, the dowager empress arranged for the marriage of Gyälsugru to a Chinese princess who came to Tibet in 710. When his grandmother died in 712 Gyälsugru took the throne as King Tride Tsuktsän (Khri-Ide-gtsug-brtsan).

Growing Arab and Turkic presence in central Asia threatened the Tibetan power there. The Arab Umayyad caliphate used Tibet and other central Asian groups as pawns to further its own political agenda. In 751 the Tibetans allied with the Arabs and Uighurs against a Chinese and Karluk Turk force at the Battle of Talas River. The Karluks defected, and the Chinese were defeated. Tibet became a regional power as a result of the battle.

Tride Tsuktsän was assassinated by two of his ministers in 755. The following year, Trisong Detsän (Khri srong Ide brtsan) (r. 756–797) was crowned king. At the same time, the An Lushan Rebellion broke out in China. The Chinese redeployed troops stationed on the border with Tibet to quell the rebellion. While China was occupied with the rebellion, the Tibetan army cut the link between Anxi and Chang'an. They used a similar ploy in 763 when Tibet attacked Chang'an and sacked the city, holding it for 15 days. With its victories against the Chinese, Tibet reasserted its power in central Asia. Hostilities between China and Tibet continued despite diplomatic efforts. China sent its nominal allies, the Uighurs, to threaten Tibet's northern border.

Meanwhile in Tibet, Trisong Detsän sought to replace the traditional animist religion with Buddhism to keep the aristocrats in check. In 770 he suppressed the nobles and invited monks from China and India to spread Buddhism. His son Mune Tsänpo (Mu-ne btsan-po) (r. 797–799) continued to support Buddhism. He forced the nobles to contribute to Buddhist monasteries, causing great resentment. He was poisoned by his mother, Queen Tshe-sbang-bza, who supported the nobles' cause. Despite this, the next two kings also supported Buddhism, punishing those who did not comply.

Tride Songsän (Khri Ide srong brtsan) (r. 799–815) struggled with the Arabs in the west and the Uighurs in the north. His successor Ralpacan (Khri gtsug Ide brtsan Ralpacan) (r. 815–838) continued to fight the Uighurs. After Tibet once again raided Chinese territory, China offered both the Uighurs and the Tibetans diplomatic marriages with Chinese princesses. This plus the Sino-Tibetan treaty signed in 823 brought 20 years of peace to the region.

Ironically, the last king of the Tibetan empire, Glang Darma (Khri 'U'I dum brtsan) (838–842), saw the collapse of Tibet's longtime enemy, the Uighur empire. In reaction to the support of Buddhism by previous reigns, Glang Darma banned the Buddhist religion and closed all the temples and monasteries. He was assassinated by a monk. After his death a struggle over succession led to civil war. In 846 the Tufan dynasty collapsed, and Tibet divided into several kingdoms, none of which rose to the power they enjoyed under the Tufan.

Korea from the Three Kingdoms through the Silla to the Koryo Dynasties

Korea's Three Kingdoms period was one of rapid and revolutionary change, unparalleled cross-cultural exchange, sophisticated artistic and intellectual endeavor, high stakes international diplomacy, and finally regional war. Its culmination with the triumph of Silla over its rivals in 676 allowed the history of the peninsula to proceed along a single and independent trajectory toward the emergence of a Korean cultural identity. But with the peninsula's unification came an end to perhaps the most dynamic period of Korean history. Not until modern times would the peninsula again be the center of such volatile and creative energies.

Scholars have a difficult time saying when exactly the three kingdoms of Koguryo, Paekche, and Silla emerged from out of the tribal confederacies that preceded them. The dates of their emergence first assigned by the twelfth-century Korean scholar Kim Pusik—57, 37, and 18 BCE for Silla, Koguryo, and Paekche, respectively—had as the primary objective the establishment of Silla precedence with little basis in historical fact. Suffice it to say that by about 300 CE the Three Kingdoms—Koguryo in the northwest, Paekche in the southwest, and Silla in the southeast—had emerged as the three dominant political units on the peninsula.

The Three Kingdoms were centers of great networks of cross-cultural exchange in northeastern Asia and beyond. Indeed, one notable characteristic of the period is the porosity of regional borders. From the fourth century Buddhism began to arrive on the Korean peninsula via the petty dynasties of northern China, which had arisen in the wake of the fall of the Han, although Paekche eventually nurtured its own relationships with the more southerly Chinese dynasties. By 550 all three kingdoms had adopted the faith with far-reaching cultural consequences.

Buddhism proved a great vehicle for another revolutionary product of cultural exchange: Chinese writing. Koguryo was adept enough in the intricacies of classical Chinese to carve the massive funeral stele for its most notable king

The eighth-century Pulguksa Temple, in South Korea, is considered a masterpiece of the golden age of Silla Buddhist art. (Tae Hoon Kang)

Kwanggaeto in 414. Soon all of the Three Kingdoms were composing their own national histories in the imported script, although these have long been lost.

Contact between the peninsula and Japan was also common in the Three Kingdoms period. From the fifth century Paekche nurtured a close relationship with the emerging Japanese Yamato court that opened up important conduits of cultural exchange. Paekche monks transferred Buddhism to Japan, and most historians agree that it was a traveling scholar from Paekche named Wangin who first brought Chinese writing to Japan in the early fifth century. Japanese-Silla relations were not so cordial. Pirates issuing from the Japanese islands routinely harassed the Silla coast, finally compelling Silla to construct massive coastal defensive fortifications.

Within a century of Buddhism's adoption by Paekche and Koguryo, adepts of those kingdoms hungry for Buddhist scriptures and knowledge were traveling far afield and bringing the fruits of their efforts back home. Silla monks would join in such endeavors following their state's official adoption of Buddhism in 527. Koguryo monks could travel overland to China but for their Silla and Paekche counterparts it often meant a sea voyage, and both of these kingdoms became adept at Yellow Sea navigation. By the eighth century large Silla communi-

ties were thriving along Tang's eastern coast, where they often served as traders between Tang and their homeland. Japanese missions to China were often heavily reliant upon such Korean maritime middlemen. Records indicate that even Arab and Persian traders began tapping into such regional networks, reaching Silla ports by the ninth century.

The level of sophistication attained in the arts and in public works stands as a testament to the degree of development and organization in the Three Kingdoms from the early centuries CE. In Koguryo, remnant stone pyramid and mounded tombs found at a series of that state's capitals reveal both that kingdom's sophisticated engineering skills and the power that its monarch had attained by 400. Perhaps its most impressive engineering achievement was the extended network of stone walls and mountain fortresses that protected its northern frontier and several times fended off massive Chinese assaults. Paekche tombs found around its several capitals in central-western Korea reveal its close relationship with Koguryo as well as the influence of the Chinese southern dynasties. But it is in and around Kyongju, the Silla capital, where the most stunning examples of rich heritage of Three Kingdoms' art and architecture are found. Revealing Silla's intimate national relationship with Buddhism, the vast majority of artistic undertakings were Buddhist in nature, while the layout of the capital itself, like Nara in Japan, reveals its debt to Chinese urban planning.

The wars of the seventh century that finally unified Korea were not strictly Korean wars at all but instead were regional conflicts for hegemony. The Sui and its successor Tang had been attempting since the late sixth century to subdue a troublesome Koguryo on their northeastern frontier but without success. Silla seized the diplomatic initiative offered by Tang's failed 645 attack on Koguryo to broker an alliance with the Chinese dynasty against both Paekche and Koguryo. The Tang-Silla attack against Paekche that came in 660 was a shock to the Japanese court, which had by now enjoyed a long and close relationship with that kingdom. It was a strong enough relationship that the Japanese court responded positively to Paekche appeals for assistance and in 663 dispatched a large force

to restore the fallen Paekche, but it proved no match for the Tang-Silla armies.

The Tang-Silla alliance moved on Koguryo with equal success, seizing that kingdom's capital and capturing its last king in 668. Partners in war, Tang and Silla parted ways with the initial peace. Tang soon revealed itself intent upon establishing a Chinese colony of the defeated kingdoms' territories reminiscent of the Han dynasty commanders who had controlled the region seven centuries earlier. Only after a series of battles between the former allies did Silla emerge in 676 as the undisputed master on the peninsula.

The unification of the peninsula by Silla in 676 was not total. Koguryo remnants re-formed in the peninsula's northeast, joining with Malgal elements to form the Parhae state. Parhae and Unified Silla shared nearly parallel life spans, with Parhae falling in 926 to the Khitan and Silla formally submitting the following year to Koryo. Although Silla and Parhae never nurtured any relationship and regarded one another warily throughout their mutual existence, upon their fall they were both assimilated into Koryo, with the exception of the Malgal element.

The wars that unified the peninsula and established Silla as the primary hegemon greatly lessened the instability of the region and in so doing eliminated a major source of its dynamism. Tang largely withdrew from Korean affairs, satisfied with the loyalty of its Silla subject. Checked in Korea, Japan also soon withdrew from continental intercourse, abandoning in great part as well its halfhearted adoption of the Chinese legal and bureaucratic systems.

Unified Silla (676-927) was more inward looking and existed during a time of political and cultural consolidation. Buttressed by its successful unification, the Silla monarchy in the eighth century reached the height of its power and prestige. Emerging from the unification wars with greater authority than ever, Silla kings set off on an energetic campaign to finally squelch the power of the entrenched aristocracy. One aspect of this was the increasing adoption of a Chinese-style bureaucracy. Silla re-organized the national territory, now including the former Paekche and Koguryo domains, into Chinese-style districts and counties and established new regional capitals, in great part

➤ CHANG POGO

Chang Pogo was a man of mysterious origins who became, for a brief period, a maritime warlord, kingmaker, and key political figure of the late Unified Silla kingdom. Although apparently Korean, as a young man Chang Pogo voyaged to Tang China, where he won distinction as a military commander. Troubled by Tang's growing social and political disorder and the suffering of its many Silla residents, many of whom were falling victim to bandits and slave traders, around 825 Chang returned to Silla. His appeals to the Silla king to establish an armed presence in the Yellow Sea resulted in King Hungdok appointing Chang the military commissioner of Chonghae Garrison, a naval command post at what is today Wando Island off Korea's southwest coast, and granting him 10,000 troops. Chang Pogo was soon a controlling force on the sea lanes between Japan, Korea, and China, as testified to by the surviving journal of the ninth-century Japanese monk Ennin (794-864). In 839 Chang demonstrated his growing power when his troops proved instrumental in seating King Sinmu (r. 839) on the Silla throne. But the powerful commander went too far when he attempted to marry his daughter into the Silla royal house. His common lineage and pretensions to power made him enemies among the capital aristocracy. It was likely such animosities that resulted in his assassination around 845. Chang Pogo stands as one of the most influential figures of late Silla, evidence of both Korean maritime skill as well as the turmoil that characterized Silla politics of the ninth century.

—Daniel C. Kane

populated by former subjects of the conquered kingdoms. The Silla king also set up Chinese-style ministries staffed increasingly by lesser aristocracy trained in Confucian learning.

While the Three Kingdoms period of Korean Buddhism had been one of continental connections and the quest for sutras, the Unified Silla period was more concerned with assimilating and harmonizing the wealth of material that had been imported. As Tang society descended into increasing turmoil, Buddhist missions to that country tapered off. Emphasis on Buddhism's state-protection aspects and the aspect of Silla as Buddha Land was deemphasized in Unified Silla

as the heightened dangers and tensions of the Three Kingdoms period passed. Instead, Confucian learning came increasingly to dominate government affairs, while Silla Buddhism sought doctrinal harmony. In late Unified Silla the textual schools of Buddhism gave way altogether before the rising popularity of Son (Zen) Buddhism among the powerful gentry of the interior.

The Silla monarchy's attempt to assert its own authority at the expense of the aristocracy was a long-term failure. From approximately 800 began a long decline of central power, replaced by regional power centers in the interior often centered around a powerful landed gentry figure with no relationship to the former ruling order of the capital region. Amid widespread turmoil in the countryside the shadows of the former Three Kingdoms fell again over the peninsula when two rebel leaders declared the foundation of Later Paekche and Later Koguryo in the early tenth century. But the peninsula was not fated to again witness an extended period of division. Later Koguryo, later renamed Koryo, was able to defeat Later Paekche and eventually receive the submission of the last Silla king in 927, again setting Korea on a unified path.

Japan from the Yamato through Fujiwara Periods

Scholars usually divide the era from 300 to 1000 CE into three phases: the epoch of a Wa/Yamato confederation (250–645 CE), the heyday of a polity modeled on principles drawn from Chinese history (645–900), and the classical or aristocratic state (900–1050) dominated by a tiny elite living in Kyoto (Heian). On the surface, Japanese politics and statecraft underwent great change in these 700 years; certainly membership in the elite, the names and sizes of offices, and the amount and means of recompense altered almost continuously. In another sense, however, the Japanese state changed relatively little: a monarch reigned with the aid of a designated marital line; a nobility aided the ruler by providing him or her with advice, commodities, and services; and local notables dictated the reach of the central government into a given region's population and resources.

During the first phase, a people known as the Wa ruled over a confederation in western Japan. The first mention of this polity comes in a Chinese dynastic history, which describes the shaman-queen named Himiko (r. c. 250 CE). She seems to have been the leader of a bloc of tiny principalities centered on large moated settlements, each controlling about 100 square kilometers, centered in western Japan. Following her demise, reliable written and material evidence of statecraft in the islands does not reappear until about 390 CE. At that time, Chinese histories write, five kings ruled western and central Japan and possibly parts of southern Korea. These kings were military leaders whose reigns always ended in warfare and who built huge keyhole-shaped tombs filled with vast quantities of iron weapons and tools. Japan is an iron-poor archipelago, and the iron as well as horse trappings, stoneware, stone-fitting technology, noble accoutrements such as gold and silver jewelry, and methods of statecraft came to the islands with Korean immigrants. By 500 the five kings had developed some court institutions, including a marital line from which the king took consorts and the use of surnames (*uji*) and titles (*kabane*) to distinguish the functions of a service nobility.

After a period of civil war during the 500s, a new house came to occupy the throne. Establishing their base in Yamato (Nara), the new kings are known as the Yamato line. They took for their consorts the Soga, a family of Korean origin, who quickly took over control of the court. The Soga remained in power until 645. The Yamato court maintained close ties with Korea, adopted Buddhism to protect the state, made alliances with about 120 local leaders known as *kuni no miyatsuko*, and initiated the development of a ranked bureaucracy. Also during the sixth and seventh centuries scribes wrote down the mythological history of the Yamato line, claiming descent from the Sun Goddess in a line unbroken for ages eternal (*bansei ikkei*).

Phase two began in 645 when the Soga were destroyed in a palace coup, and the new leaders desperately attempted to centralize and militarize the nascent state. The coup came as a reunified and vigorous China—under the Sui dynasty (589–617) and Tang dynasty (617–906)—launched massive expeditions into Korea, putting pressure on rulers in Korea and Japan. Following the coup, the Japanese court tried to intervene in international politics with disastrous consequences: the loss of 27,000 troops at the Battle of the Paekchon River in 663. Fearing an imminent invasion, the court and local notables rejected the losing leadership, and Prince Oama seized the throne from his brother in the civil war of 672. Renamed Divine Sovereign Tenmu (r. 672–686), he and his consort Jitō (r. 686–697) borrowed and adapted Chinese-style institutions to strengthen their territory against a possible assault from China or Korea, unified under the hostile Silla dynasty (668–918).

The Taihō Code, completed in 701, laid out the principles of political control. The new government, now located in a Chinese-style rectangular capital laid out along the lines of the compass (first in Fujiwara and then in Nara), established a large hereditary bureaucracy that was appointed, ranked, paid, and dismissed according to Chinese principles. To support the sovereign, his court, and the bureaucracy, the government adopted and modified the Chinese idea of registering the populace in a census and required the people to farm a certain amount of

THE LIFE OF THE JAPANESE HIGH ARISTOCRACY

In the late 1980s two massive archaeological finds near the imperial palace at Nara revealed in the most concrete form yet available what life was like for the high aristocracy. Japanese archaeologists believe that they uncovered the estate of Prince Nagaya (684–729), grandson to Divine Sovereign Tenmu (r. 672–686). Nagaya held the lofty status of the junior third court rank, occupied by only a few people at that time. His compound housed 4 wives, 18 children and siblings, and their 4 wet nurses. The estate ranged over 15 acres and contained 30 buildings. Among the buildings was a main office for Nagaya's state-appointed staff. They oversaw the feeding and clothing of his family, employing cooks, rice wine brewers, yogurt makers, firewood collectors, seamstresses, dyers, potters, metal pot makers, and movers, among others. Estate workers included plasterers, tanners, bronze casters, weapon makers, and sculptors of Buddhist statues. Nagaya's household also contained attendants to care for his dogs, horses, and falcons; diagnose and treat his family's illnesses; and manage the system of interest-bearing rice loans that financed his businesses. In addition to his household, Nagaya possessed fields scattered throughout the region, an ice storehouse, lumberyards, a salt bin, and a charcoal-firing center. He received commodities such as rice, dried fish, and salt from about half of Japan's 66 provinces. Ironically, the artifacts reveal that Nagaya's consort Princess Kibi (?–729), granddaughter of Tenmu, daughter of one sovereign and sister to two more, was even richer than her mate, who was murdered in a political intrigue in 729.

rice paddy and pay a variety of poll taxes. This system functioned fairly well for about 120 years, although evidence suggests that recurrent epidemics of smallpox and other diseases as well as frequent famines resulting from drought and environmental degradation had begun to shrink the tax base by 800.

During the 800s myriad problems surfaced to end the Chinese-style system. Not only did the registered population shrink, resulting in fewer taxes, but the elite spent lavishly on new temples and capitals and on wars in northeastern

Japan. The overburdened populace began to resist taxation violently, and tax collectors replied in kind. Incidents of domestic violence spiraled. Finally, the old class of local notables, numbering about 550 at their height, either fell into poverty or refused to cooperate with the distant court ensconced in the half-finished capital at Heian.

During phase three beginning about 900, the ruling elite of royal and aristocratic families decided to retreat from direct control over the land and people of Japan and shift to a system of tax farming. About 66 provincial governors served four-year terms during which they collected as many tax items as they could from a decimated and beleaguered commoner class. To supplement their income, the central elite established some estates (lands known as *shôen*). At court, the sovereign fell under the sway of a new marital line—the northern branch of the Fujiwara—who dominated politics. Decision making at court was essentially unchanged; a council of aristocrats met before the sovereign and discussed policy issues. This new attenuated system held sway until about 1050; civil aristocrats and religious institutions produced a brilliant classical culture symbolized by the *Tale of Genji*, while tax farmers collected all they could from the hapless populace. Although the scope of statecraft had changed greatly between 300 and 1000, there was also continuity: the royal family usually ruled with the aid of a marital alliance to a strong family and a class of aristocrats, and the elites' wealth and power were always constrained by their ability to cooperate with locally prominent families who controlled the common people.

Japanese Embassies to China

From the late sixth century to 838, the Japanese government sent a series of great cultural missions, or embassies, to Sui and Tang China to study and absorb China's civilization, which the Japanese government considered the epitome of refinement. These embassies were simultaneously cultural missions and trading expeditions. They were transported by flotillas of ships carrying merchandise as well as diplomats, students, and monks. Each embassy stayed in China for several years, some as much as a decade or more. Japan's culture has many roots in China. Buddhism, first introduced to Japan in the mid-sixth century from China and Korea, was used primarily as a tool of state power. Imperial prince Shotoku (b. 574) was a great promoter of State Buddhism and sent embassies to China to study Chinese civilization in depth.

These early missions from Japan started in China's Sui period and ended 260 years later. They are officially known as the Embassies to Sui China (*Kenzuishi*) and the Embassies to Tang China (*kentoshi*).

There were 5 missions to Sui China, starting in 607, and then 18 or 19 to Tang China, with the last ship in 838 carrying the priest Ennin. A mission planned with Sugawara no Michizane in 894 was cancelled owing to internal problems in China, and for a time that was the end of these voyages. The main goals of these missions were cultural exchange and trade. Most included Japanese court officials, diplomats, merchants, engineers, and many Buddhist scholars and student-monks. They brought many innovations back to Japan, including the Chinese vocabulary and the new ideas it encapsulated. In these early centuries, many things found their way to Japan via the Silk Roads, Persia, Korea, and China.

A special museum, the Shoso-In, was built in Nara in the compound of the temple Todai-ji to hold these imperial treasures. It became a vast repository of more than 9,000 items, and even today its remaining treasures depict a period of vibrant cross-cultural activity and a sophisticated cosmopolitan culture in Tang China. Recently, in 2004, the stone epitaph of Jing Zhencheng (the posthumous Chinese name of a Japanese envoy who visited China in the early

ENNIN'S OBSERVATIONS ON HIS JOURNEY TO CHINA

Ennin was one of the most important Buddhist clerics in Japanese history, but his fame derives, to a large degree, from the diary he kept during his sojourn in China with the last great Japanese embassy. Ennin was born in Shimotsuke (present-day Tochigi) and began his religious training at age nine. Later he went to Mount Hiei and became a disciple of Saicho, founder of the Tendai sect. In 838 after two failed attempts due to bad weather, he reached China as a student-monk. He departed from the official mission and traveled alone with his servants in various areas of China and Korea, keeping his keen eyes on the local culture.

He described everyday life in the temple and the market place and, like a modern-day ethnographer, wrote details about customs and institutions, administration and politics. Dr. Edwin O. Reischauer translated Ennin's famous diary *The Record of a Pilgrimage to China in Search of the Law* (*Nitto Guho Junrei Koki*). Ennin returned to Japan after nine years.

On his return he established many rituals special to Tendai, the so-called Secret Tendai Teachings (*taimitsu*). He also brought back special rituals for chanting prayers to Amida Buddha and a five-tone recitation (*jogyodo nembutsu*) that is still practiced widely in Tendai communities. At age 61 he became the third head of the Tendai sect at Mt. Hiei after Saicho. He was given the posthumous title Jikaku Daishi.

Rubbing taken from a Tang dynasty stele of the Japanese monk Ennin. Ennin is probably the most famous Japanese Buddhist pilgrim to China. (Werner Forman/Corbis)

eighth century) was discovered in Xian, China. The discovery, announced by Northwest University in Xian, is probably the oldest proof of these early missions. The first mention of the name "JAPAN" on this epitaph is also remarkable. Xian was known as Chang'an in the Tang dynasty.

Among the embassies, the second Sui mission, led by Ono no Imoko, was very successful. On his way back an envoy accompanied him from China. The third Sui mission, with Takamuko no Kuromaro and the monk Somin, had a profound impact on Japan's Taika Reform of 645 and the subsequent development of Buddhism

in Japan. Abe no Nakamaro (698–770) left for China in 718, together with Kibi no Makibi. Nakamaro never made it back to his homeland and left behind many tanka poems about being homesick. He won the confidence of the Chinese emperor Xuanzong and was sent to Annam as a governor.

In 803, the priests Saicho (founder of Tendai Buddhism) and Kukai (Kobo Daishi, founder of Shingon Buddhism) boarded ships for China. Both later became very important figures in promoting esoteric Buddhism in Japan. Kukai's ship, on the journey back, got caught in a severe

storm. He threw a Buddhist pestle (*sankosho*)—given to him by his Chinese teacher Keika—into the sky toward the east in the hope that it would land in an ideal place for him to begin preaching Shingon Buddhism. He later found the pestle on a pine tree on Mount Koya (Koyasan) in 816, where he then founded his famous monastery. Kukai also studied civil engineering in detail and is famous for introducing water-regulating systems in Shikoku and other parts of Japan.

Traveling to China was a risky venture owing to weather conditions, wars, and piracy. The vessels were called *kentoshi sen* (“ships of the missions”). They were rather small, and many never returned. Some were shipwrecked, and the envoys ended up in Southeast Asian countries.

The Japanese embassies to China were a cultural umbilical cord that facilitated the transmission of Chinese culture to Japan. But as with the physical umbilical cord, Japanese culture outgrew the need for the embassies, and they were discontinued.

Culture and History of Indigenous People of Northern Japan

The annexation of northern Honshu to the southern-based imperial state was a union from the point of view of the south but a division for the north: gradual breaking of the link between Hokkaido and the main island, Honshu, where a common language and culture as well as a loose federation of peoples existed. The political strength and cultural autonomy of the Ainu-speaking populations began to erode as the Japa-

nese Yamato state expanded; their southern border was constantly pushed north, eventually leaving only the tip of Honshu as Ainu territory by the thirteenth century.

William Farris provides the following translation from the *Nibonsboki* (*The Chronicles of Japan*, compiled 720), the earliest Japanese written record, and its report on an indigenous nation known as Hitakami: “Among the eastern barbarians are the Hitakami. In that country men and women are both tattooed, and are brave. They are the Emishi. Their land is huge and rich. We must conquer and take it.” The initial conquest of the north by Emperor Keiko occurred in the third or fourth century, but it was not until the mid-seventh century that the northern way of life transformed in response to the invasion.

In the seventh century, influenced by the sedentary agricultural Yayoi culture of the south, Satsumon (a culture characterized by incised-motif pottery) emerged connecting Hokkaido and northern Tohoku (the northern half of northern Honshu) following millennia of an advanced nomadic foraging way of life known as Jomon (a culture characterized by potteries decorated with elaborate rope pattern), the first and oldest in Japan. The Satsumon lingered in the north for six centuries, while the prototype of modern Ainu culture, partially influenced by seal-hunting Okhotsk culture, emerged toward its end.

Though the Emishi population consisted of diverse ethnic components, it included speakers of the Ainu language, who left their footsteps throughout northern Japan. Ainu linguists identified indigenous place-names that persist and ensure a basic continuity in Hokkaido, Sakhalin, the Kuriles, and northern Honshu, such as those displayed by the words *nay* and *pet* designating rivers. Moreover, a considerable number of personal Emishi names found in Japanese records from the seventh century onward are Ainu or Ainu-like. The best example might be Aterui, a tragic hero of the Battle of Subuse: “the bandit chief” who led the Emishi and defeated a large imperial army along the Koromo River (a branch of the Kitakami River in Iwate Prefecture) in 789. Native speakers of Ainu assert that his name in Ainu is rendered *at-oro-i*, meaning “the place to soak elm bark in water” to make the *atushi*,

the traditional Ainu jacket. Aterui was taken to Kyoto and executed by the court in 802.

However, as the Yamato progressed northward, native tongues gradually faded away, and their mutual intelligibility in Ainu was confined to farther north. As the conquest of the north by the Yamato relied on the tactic of using barbarians to pacify barbarians, powerful chieftaincies based on the combination of heredity and merit emerged, ruling the Ainu and other indigenous populations connected by a large trade network extending to the Amur River region in Siberia. These powerful northern lords are known as *Fushu*, having compromised their native status to receive an official rank or recognition in the Yamato bureaucracy called the Ritsuryo system, which imposed tribute and labor taxes as well as a military draft on the locals.

One of the most controversial issues in the history of Japan concerns the nature of the socio-political relationship between the Emishi/Fushu with the Yamato. However, contemporary scholars posit that an indigenous quasi-state existed in northern Honshu, which was not entirely within the jurisdiction of the Japanese state. Existence of a surplus economy, servitude, a great military capability, and hieroglyphic writing, counting, and recording systems support the high degree of political structure among the Emishi. Although their indigenous state was not unified and centralized, it was capable of great solidarity among the loosely federated polities at times of war against the Yamato.

Moreover, the dual identity of the Fushu was also a weakness, as the political tension in the north constantly increased. Their identity dilemma was the cause of several major rebellions in the eleventh century, including the Former Nine Year War (1050–1062) that involved a hereditary district magistrate appointed by the imperial state, Abe Yoritoki, whose independence had reached the point that he was neither paying taxes nor providing men for labor services.

The conflicts among the Fushu clans contributed to further division in the north, which helped the imperial state gain more control. By the early thirteenth century, Japan's northern frontier shifted to the northernmost region of

➤ ATERUI—INDIGENOUS HERO

Aterui is the first Ainu indigenous leader whose name is known to history. His name first appears in the *Shoku Nihongi* (*The Continuation of the Chronicle of Japan*) in the paragraphs referring to the imperial army's defeat at the Battle of Subuse in the eighth year of the Enryaku era (789 CE) as "bandit chief i-no-aterui" in which *i-no* designates "belonging to other, savage race in the East." He is also noted as "i-no-ohtsuka-no-kimi-aterii" (large-tomb chief Aterui of Eastern savage race) in the *Nihongi Ryaku* (*The Summary of Japanese Chronologies*) in the paragraphs describing his execution.

In 802 CE, Aterui appears to have voluntarily accompanied the imperial grand official Sakanoue Tamuramaro to Kyoto. Tamuramaro began to build Isawa Castle in 802, which was located at the center of Emishi territory in Isawa region, as part of the imperial government's plan to settle 4,000 vagrants there. *The Shoku Nihongi* records that Aterui and his chief lieutenant, More (Ainu: morai, meaning "quiet river"), "surrendered" with their 500 companions. Tamuramaro proposed to the court that these Emishi leaders be pardoned and returned to their homeland to assist him in peacemaking with the "rebels." But the court nobles replied that they could not be trusted at all and that to send them back was to feed the tiger and leave potential harm. Aterui and More were arrested and beheaded at Moriyama in Kawachi country near Kyoto in the eighth month of the same year.

—Sakurako Sherry Tanaka

Honshu, Tsugaru (Aomori Prefecture), and the indigenous population there and in Hokkaido came to be called Ezo. The lineages of the Fushu clan and the official deputy status continued in Tsugaru, as the chief of the Ando clan was appointed as Ezo Kanrei, "the lord for the Ezo." Others fled farther north to Hokkaido, as testified by some Ainu in Hokkaido who have family oral histories tracing their ancestors to northern Honshu.

Yet the maternal line contributed to the continuity of Ainu heritage in northern Honshu,

evidenced by the matrilineal system of the Fushu clans who often lost their men in war. This is understandable, however, considering the parallel descent system practiced by the Ainu whereby the male line of descent was passed down from father to son and the female line from mother to daughter. The members of the maternal descent group had a distinct collective consciousness as relatives descended from one old woman, which defined permitted degrees of relationship for marriage: a man could not marry a woman who belonged to the same descent group as his mother. A similar dual-descent system was also found throughout the Japanese archipelago before the enforcement of Confucianism in the Edo period.

■ Introduction: Early Medieval Inner Eurasian Empires

In late antiquity (300–600 CE) and the early medieval age (600–1000 CE), the peoples of Inner Eurasia were the principal scourges of the sedentary Eurasian states. Inner Eurasia consisted of the great area of grasslands and forests north of the Roman, Persian, and Chinese empires. On this great expanse lived pastoral tribes on the grassy steppe, with farming villagers inhabiting the forested edges of the grassland.

The relationship between the pastoral peoples of Inner Eurasia and the agricultural empires to the south fluctuated with the comparative strength of the pastoral and agricultural peoples and the climatic cycle. During the relatively warm and moist period, which included the last three centuries BCE and the first two centuries CE, both the pastoral peoples and the agricultural empires prospered. The agricultural empires maintained strong and stable governments and maintained their frontier defenses at a high degree of efficacy.

During this period, the steppe and the agricultural lands engaged in an often mutually beneficial trade and cultural exchange. But by the third century CE, the climate turned drier and colder, causing hardship to both the steppe and

the agricultural empires. During this Dark Age Cold Period, the farming lands suffered. Crop failures and natural disasters in the agricultural empires led to hunger and rebellion, and because the lessening of revenue supporting the large military establishments that the defense of the northern frontier required, political instability and civil war occurred.

But the pastoral peoples also suffered. The grass on which their herds subsisted dried up, and the carcasses of their starving animals sometimes littered the steppe. Hungry pastoral hordes forced their way through the weakened imperial defenses and pillaged the equally desperate farming folk.

The Huns were among the first of these hordes. The Huns are thought to have descended from Xiongnu nomads who had been defeated by the forces of the Han dynasty. The Huns then moved west and, by the beginning of the fourth century CE, pastured their herds north of the Caspian Sea. When the climate turned cold and dry, the Huns then attacked their neighbors to the west, the Goths. The Goths clamored for admission to the Roman empire and destroyed a Roman army in 378. This Roman defeat set in

motion more than a century of turmoil during which Goths and other German tribes as well as Alans and Huns ravaged the Roman empire and erected new kingdoms on the ruins of the western half of the empire.

Many of the pastoral peoples settled down in the new environment to form a new aristocracy governing the sedentary farming population. The Toba, a people of mixed Mongolian and Turkish origin who conquered most of northern China, were such a people. The Toba ruled northern China as a strong and prosperous state for about a century and a half (386–534). Over the six or seven generations of their rule, the Toba became assimilated into Chinese civilization and disappeared as a distinct ethnic group.

The Toba, who assumed the responsibility for defending the farming Chinese against more pastoralist invasions, fought and defeated (429) the Juan Juan (Ruan), driving them from their homeland in Mongolia. The Juan Juan then moved west, setting in motion a domino-like process that eventually reached Europe and the Roman empire. When the descendants of the Juan Juan reached Europe (557), they, now known as the Avars, pastured their herds on the debris of Roman Panonia (where Hungary is today) and proceeded to harass the Byzantine empire. In 626 the Avars joined the Persians in besieging Constantinople but were defeated by the Byzantine fleet. Returning to Panonia, they gradually settled down as farmers.

On their migration westward across the steppe the Juan Juan encountered the Hephthalites, who are also thought to have migrated from the steppe north of China to central Asia. The Hephthalites, also known as the White Huns, conquered much of central Asia before 425 CE and there began a conflict with Sassanian Persia, with whom they fought intermittently for nearly a century until their final defeat by the Persian king, Khosrau. From their capital, Bamiyan (in present-day Afghanistan), they invaded India. Their attacks played a large role in the dissolution of the Gupta empire.

When the Toba expelled the Juan Juan from Mongolia, they created a power vacuum that was eventually filled by the Gok-turks, or Turks, who created a great steppe empire stretching from Mongolia to the north shore of the Black Sea.

This empire was primarily pastoral but grew wealthy by levying tribute on the forest and farming peoples whom they dominated and collecting a toll from the reviving silk route trade. The Gok-turks established the first Turk empire, which lasted 80 years (552–630). From 581 to 630, the empire was split into an eastern and a western Turk empire. Incessant civil war between the two empires coupled with attacks by the revived Chinese empire under the Tang dynasty led to the demise of the first Turk empire.

Anarchy and insecurity again characterized the steppe until in 683 Kutlugh, a chieftain from the area north of China, united the Turkish tribes in Mongolia to form the second Turk empire, which endured for half a century (683–734). This empire conquered most of the area that the first Turk empire had ruled. Like its predecessor, the second Turk empire supported itself through tributes from subject peoples and through tolls on trade. Also, like its predecessor, the second Turk empire split into eastern and western wings. This empire is said to have lost its erstwhile nomadic vigor and succumbed to Chinese intrigues, by which the leader of the empire was poisoned and the empire fell into disarray.

Another Turkish empire on the eastern steppe was that of the Uighurs. The Uighur empire emerged in Mongolia when the second Gok-turk empire fell (634). During the years of the An Lushan Rebellion, the imperiled Tang dynasty requested assistance from the Uighurs. In rendering that assistance, the Uighurs looted the accumulated wealth of the Tang by sacking the Tang capitals, but they did save the Tang, who then were required to deliver annual tributes to the Uighurs. The Uighur empire became a commercial empire and protected the Sogdian merchants who dominated the transhemispheric trade of the Silk Route. The Uighurs, or at least their ruling class, converted to Manichaeism, and the Uighur empire became, for nearly a century, the international protector of the Manichees.

When its erstwhile subjects, the Kyrghiz, destroyed the Uighur empire in 744, the Chinese launched a savage persecution of the Manichees, leading to their virtual extirpation in China.

Perhaps the most significant and certainly the most long-lived of the Inner Eurasian empires in the early medieval age was that of the

Khazars. The Khazars, another Turkish people, were a major power for about three centuries, from the 620s to their destruction by the Kievan Rus about 965. Their empire, which was centered in the grasslands north of the Caspian and Black seas, effectively stopped Muslim expansion northward and played a major role, in alliance with the Byzantine empire, in curbing Muslim advance into Anatolia and the Caucasus. The Khazar empire is unique in that it adopted Judaism as its official religion.

The Uighur empire and the Khazar empire are both subjects for separate essays in this encyclopedia.

The Uighur Empire

The Uighur empire dominated much of east-central Asia for nearly a century, from the mid-740s to 840 CE. The Uighurs were a group of tribes who spoke a Turkic language and inhab-

ited the steppe region of what is now western Mongolia and eastern Turkistan. They rose to prominence in the 740s CE during the decline of the Tork empire. Forming a coalition known as the Tokuz Oghuz (“the nine tribes”), the Uighurs overthrew the Torks. They then turned on the Basmils and Karluks, two tribes formerly allied with them, and forced them to migrate to the west. (The Karluks would settle in what is now eastern Kazakhstan and Kyrgyzstan; some of their descendants founded the Karakhanid empire of the eleventh century.) The Uighur leader Kutlugh Bilgä of the Yaghlagar clan assumed the title of khagan in 744.

Within a short time the Uighurs controlled much of Mongolia, eastern Turkistan, southern Siberia, the Tarim basin, and Ferghana. Through their domination of large segments of the Silk Roads, the Uighurs gained access to a wide array of precious metals, gems, textiles, agricultural products, and other important goods. The Uighurs were more open to influence from their sedentary neighbors than their predecessors, and a number of important cities sprang up in their territory, including their capital of Ordu Balik (Karabalgasun).

The early Uighur khagans developed close relations with the Tang dynasty of China with whom they traded Siberian furs and horses for valued Chinese luxury goods, but the relationship was often strained due to Uighur ambitions. Uighur khagans demanded, and occasionally received, recognition as equals of the Chinese em-

MANICHAISM IN CENTRAL ASIA

The conversion of the Uighurs to Manichaeism was not without controversy. When the Khagan Itichien attempted to impose the faith in the 770s, he and many of his family were assassinated, and his successor Tun Alp Kutlugh led an anti-Manichaean reaction. Ultimately, however, Manichaeism triumphed, and its adoption as a state religion transformed the Uighur khaganate. Its priesthood led to the establishment of schools, temples, and libraries. Some scholars believe that as much as a third of the population of the empire's cities was literate.

Before archaeologists began a serious study of central Asia in the last century, knowledge of Manichaeism, a dualistic religion shaped by Gnostic, Judeo-Christian, Zoroastrian, and Buddhist influences, was limited largely to hostile writings by such authors as St. Augustine of Hippo. A number of important excavations at such locations as the oasis town of Turfan have unearthed dozens of Manichaean scriptures that describe the faith's doctrines, rituals, and organization, giving contemporary scholars a much more complete view of Manichaeism and its history.

—Brian Gottesman

perors; the Chinese, for their part, did their best to buy Uighur goodwill with gifts (including royal brides). On several occasions, usually allied with one Chinese faction or another, the Uighurs invaded China proper and sacked Chinese cities.

The Uighur khaganate was home to a dizzying array of religious sects and ethnic groups. Turks, Arabs, Persians, Sogdians, Tibetans, Chinese, and Jews all made their home in the cities along the Silk Roads. The so-called Nestorian Christianity of the Assyrian church established a foothold in Uighur territory, as did Zoroastrianism and several varieties of Buddhism. Jewish merchants such as the Radhanites crossed Uighur territory on their land routes to China and may have established Jewish colonies all along the Silk Roads. Likewise, Islam came to the region initially through traveling merchants.

Of particular importance were the adherents of Manichaeism, a dualistic religion founded in third-century Mesopotamia whose adherents, fleeing Muslim persecution, found refuge in Sogdiana and Ferghana. Sogdian merchants, who formed much of the administrative, diplomatic, and mercantile class in the Uighur khaganate, spread the religion among the Uighur elite, leading to Manichaeism becoming established as the state religion in the early ninth century. Manichean culture and philosophy flourished under Uighur rule, and the Uighur khagans eventually saw themselves as protectors of Manichean communities beyond their borders.

The ninth century saw a steady decline in Uighur military might. The urbanization of the ruling class alienated them from the nomadic tribes from which they had once derived their support; the empire became increasingly divided between the urban and pastoral segments of the population. From 820 on parts of the empire were in constant revolt, and in 840 after a series of famines and plagues a Kirghiz army sacked Ordu Balik and destroyed the Uighur empire. Uighur tribes scattered throughout Siberia, northern China, and central Asia. In China and the Muslim Middle East where Manicheans were seen as Uighur agents, savage persecutions of their religion led to its virtual disappearance. The Silk Roads were now threatened by bandits and hostile tribes, and the Kirghiz were unable or unwilling to establish control over the region

to the same degree as their predecessors. Ultimately, the fall of the Uighur khaganate led to a power vacuum in central Asia that contributed to the collapse of transcontinental trade in the tenth century.

The Empire of the Khazars

From the early seventh to after the mid-tenth century, the Khazar empire ruled most of the area in present-day Ukraine, the Caucasus, and the steppe near the mouth of the Volga. For these three and a half centuries, which roughly coincided with the span of China's Tang dynasty, the Khazars were one of the great powers of western Eurasia, on a par with the contemporary Carolingian empire.

The Khazars were a seminomadic tribal federation that founded a powerful empire in what is now southern Russia, the Caucasus, Ukraine, and western Turkistan. Their origins are somewhat unclear. Although they appear to have spoken a Turkic language, they were probably a conglomerate of disparate ethnic groups, including migratory Hunnic people and various autochthonic populations.

The Khazars were subjects of the western Tork empire, which dominated the Eurasian steppes from the mid-500s until the mid-600s CE. A Khazar army rode with the Byzantine Emperor Heraclius against Persia in 628, but it is unclear whether they were independent at this time or still subject to the Torks. By 650, however, the Tork empire had collapsed, and an independent Khazar khaganate began its expansion, defeating the Bulgars and Sabirs and coming into conflict with the expanding Umayyad caliphate in the Caucasus Mountains.

► THE KHAZARS CONVERT TO JUDAISM

Sometime during the eighth or ninth century, the Khazar ruling class and much of the population (who had previously been predominantly Turkic shamanists) converted to Judaism. Jewish colonies had existed around the Black Sea since ancient times, and Jewish merchants were quite influential along the Khazar-dominated branch of the trans-Eurasian trade network. Various accounts of the conversion survive, including the correspondence between Hisdai ibn Shaprut (a tenth-century Spanish rabbi) and the Khazar king Joseph, the Schechter Text, a letter composed by a Khazar and discovered in Egypt in 1896, and the writings of various Muslim scholars such as al-Masudi and ibn Fadlan. The extent and timing of the conversion is hotly debated among scholars; however, the recent discovery of coins minted in imitation of Arab dirham and dated 838 that bear the legend “Moses is the Prophet of God” suggest that the conversion occurred by that date. Moreover, the writings of ninth- and tenth-century rabbis suggest that Khazar Jews had extensive contacts with Middle Eastern Jewry.

Scholars debate the impact of the Khazars on the genetic makeup of East European Jews. For some time it was fashionable to assert, as Arthur Koestler did, that the Khazars were the primary ancestors of Ashkenazi Jewry. Recent studies, however, have shown that while some Ashkenazi Jews may have Khazar ancestry, they are primarily a Middle Eastern people closely related to other Jewish populations.

—Brian Gottesman

The Khazars allied with the Byzantine empire again to combat the growing Muslim threat. Two eighth-century emperors, Justinian II and Constantine V, took royal Khazar brides. In the 720s and 730s the Khazars became embroiled in a bloody conflict with the Umayyad caliphate that resulted in a nominal victory for the Muslim army. So heavy were the losses inflicted on the caliph's forces that they had to withdraw without leaving a garrison; shortly thereafter the Umayyads would fall to the Abbasid revolution.

Sometime in the late 700s or early 800s, under pressure by both Muslims from the caliphate and Christians in Byzantium, the Khazar rulers

and much of the population adopted Judaism. At their height around 800, the Khazars controlled a vast swath of Eurasian territory from their capital at Atil (near present-day Astrakhan). Dozens of tribes, including the Alans, Oghuz, Pechenegs, Magyars, and Volga Bulgars and various Georgian principalities were vassals. The Khazar cities, including Atil, Balanjar, Samandar, Sambata (Kiev), Tamatarkha (Tmutarakan), and Kerch, became major trading hubs and centers of production for pottery, wool, honey, and other export goods. The Khazar government levied a 10 percent tariff on all foreign merchants, including those engaged in the lucrative northern European slave trade.

The Khazars had a dual kingship; authority was divided between the spiritual king (*Khagan*) and the military king, theoretically inferior in rank but exercising most day-to-day authority over the government (the *Bek*). Various officers, including the *Jawysbyghr* and *Kundur* (whose specific duties are unknown), assisted in the management of the khaganate, as did military officials called *tarkhans*, local governors called *tuduns*, and an ecumenical supreme court consisting of members of all major religions within Khazar territory.

During the early 900s Khazar power began to decline. Several rebellions by client peoples were put down by the Khazar rulers Benjamin and Aaron II, and the khaganate enjoyed a brief period of renewed authority under Joseph. The alliance with the Byzantines, however, had long since collapsed, and Constantinople switched its support to the nascent Rus, the Pechenegs, and other tribes, beginning to press on Khazaria's borders. The Volga Bulgars asserted their independence around 920. The Pontic steppes were by that time dominated by the Pechenegs, who had ousted the Khazars' Magyar allies (who migrated westward to found Hungary). Kiev, a Khazar town since the 700s, fell to the Rus sometime in the early 900s, and its prince Svyatoslav dealt the death blow to the Khazar empire around 969, when he sacked its capital Atil. Khazar politics existed in the Crimea until at least 1016, when they were conquered by the Byzantines, and tantalizing (if ambiguous) references to Khazars in the Caucasus and Black Sea region appear as late as the 1200s.

■ Introduction: European States and Empire, 650–1000

Early medieval Europe was ruled by various empires and minor kingdoms. This world was marked by instability as well as ever-changing and disappearing borders. There were various reasons for the instability that the population of early medieval Europe endured. Although the first wave of barbarian invasions were well past by the seventh century, there still tended to be a great deal of infighting among the petty kings and emperors of Europe. The Church had fought off the major heretical challenges of previous centuries such as Arianism, but it still struggled with its own organization and with its relationship with the political authority. There were also economic stresses; the prosperity of Rome's glory days had not carried over into the early Middle Ages.

The heir to the Roman empire, Byzantium, did not fare as well. The powerful Byzantine state that Justinian I (r. 527–565) left—which included nearly all of the Mediterranean basin including Italy, Greece, Anatolia, and much of North Africa—would steadily lose ground after the reign of Heraclius (r. 610–641). By the eleventh century, Byzantine territory had been reduced to the Greek peninsula and a small area around the city of Constantinople.

The kingdoms to the east of Byzantium are fairly difficult to map since there were few pre-

cise borders or frontiers. The territories north and south of the Danube River were controlled by various peoples at different times. Some of the most prevalent were the Slavs, Avars, Bulgars, Magyars, Armenians, and Georgians. Farther to the north and the east, the rulers of Poland, the Khazars, and Keivan Rus wielded significant power and influence in the early Middle Ages. Although rarely discussed in traditional European history, the states and kingdoms to the east had a significant impact on the politics and culture of the Middle Ages.

By the middle of the seventh century, Britain, the farthest outpost of the old Roman empire, was divided into a number of kingdoms. The most notable were Wessex, East Anglia, Kent, Mercia, and Northumbria. By the beginning of the eighth century, all were Christian. Much of Anglo-Saxon England, however, was invaded and occupied by Viking raiders. The southern and western regions (particularly Wessex) under the leadership of King Alfred (r. 871–899) were able to successfully resist the Viking incursions. By the middle of the tenth century, all of England was under the power of a single king.

Before the tenth century, Scotland, Wales, and Ireland also became divided and politically unstable. Ireland was ruled by the *tuatha* (petty

THE VIKINGS—EMPERORS OF THE SEA

The Vikings are one of the least understood and most maligned peoples of the early Middle Ages. The Viking peoples of Scandinavia left too few sources prior to the eleventh century to reconstruct a trustworthy account of their political culture. However, based on outside sources and recent archaeological evidence, it is possible to generate a broad history for the early Middle Ages. Although there was virtually no unity from the seventh to ninth centuries, Northmen from their bases in Norway and Denmark conquered and settled in numerous areas, from Iceland and Greenland to England and Francia. Because of their ability to navigate both the open sea and narrow rivers, the Vikings could travel virtually anywhere in Europe and beyond. Rather than the barbaric reputation they carry today, they were, in fact, traders and explorers as much as they were raiders. Their impact was felt as far south as the Muslim world of the Middle East and as far west as the New World.

—Jace Stuckey

kingdoms). In Wales, the rulers were successful at fighting off most of the Viking invaders, but tremendous infighting led to significant weaknesses that the English would eventually exploit. The Picts, a Gaelic-speaking group from northern Ireland, along with the Britons of Strathclyde inhabited the area that became Scotland. Although the Scots were able to resist a push north by the English of Northumbria in the eighth century, the Vikings occupied many of the northern islands and territories during the ninth century. Only after the eleventh century was Scotland able to achieve a greater degree of stability and autonomy.

On the continent, in the eighth century, two fairly weak kingdoms would give way to much stronger ones. In Spain, the Visigothic kingdom would be completely overrun by Muslim forces that had already conquered the whole of North Africa. In Gaul, the Merovingian dynasty of do-nothing kings gave way much more peacefully to the Carolingians when Pippin deposed the last Merovingian king Childeric III in 751.

This transition ushered in what historians have labeled the Carolingian Renaissance. The re-

naissance was made possible by the political support of, arguably, the most powerful empire in Europe after the fall of Rome and prior to the turn of the new millennium. Under its greatest king and one of early medieval Europe's most influential men, Charlemagne, the empire reached its greatest extent. He defeated the Lombards in the south, the Saxons of the north, and the Avars of the east. Charlemagne's empire included most of modern-day France and Germany as well as parts of Italy and eastern Europe. Charlemagne opened a number of Cathedral schools and helped expand learning in the West. However, infighting and civil war would lead to the collapse of the empire after Charlemagne's death. In 843, the empire was split between Charlemagne's three feuding grandsons. The West would be inherited by the Capetian dynasty in the late tenth century but in reality would be ruled by the powerful regional nobles until the twelfth century. The East would retain the title Holy Roman Empire and pass to the Ottonians in the tenth century.

In Italy, before the year 1000, political control shifted from one group to another. Shortly after the death of Justinian I in the sixth century, much of the Byzantine territory in Italy was lost to the Lombards. However, several major cities in the north such as Venice and islands and lands in the south (i.e., Sicily and Sardinia) remained in Byzantine control through the eighth century. The Lombards set up a sophisticated political system that centered around major cities. They did not, however, control Rome, as this was part of the Papal States. This territory in central Italy was directly ruled by the pope. Charlemagne's conquest of the Lombards in the eighth century was in part to aid the pope, who was continually threatened by Lombard aggression from the north and the south against the Papal States. Charlemagne quickly placed Franks in many duchies and bishoprics. After the disintegration of the Carolingian empire in the ninth century, the German and Ottonian presences in the tenth century would provide a semblance of political stability.

The world of early medieval Europe scarcely resembles its modern counterpart. That does not, however, discount the critical impact that the culture had on the later Middle Ages as well as the modern political landscape that exists today.

The Byzantine Empire, 641–1025 CE

The seventh and eighth centuries were a period of unparalleled crisis for the Byzantine empire, marked by invasions on all borders, civil war, and the religious controversy of Iconoclasm. Eighth-century emperors developed a successful defense strategy that laid the foundations for a remarkable recovery. Under the Macedonian Dy-

nasty between 843 and 1025, Byzantium regained territories lost to the Arabs and incorporated much of the Balkans into the empire through a strong centralized imperial system. In an age of cultural revival, imperially sponsored missionaries converted emerging nations to Orthodox Christianity, spreading Byzantine cultural and political influence.

The seventh-century successors of Heraclius faced continuing losses to the Arabs. Arab forces completed the conquest of Egypt and North Africa, inflicted devastating annual raids throughout Asia Minor, and by the end of the seventh century began to attack the most important Byzantine cities by sea. At the same time, Slavic tribes migrated into the Balkans and Greece, and the Bulgars settled north of the Danube, making imperial control impossible. Emperor Constans II (r. 641–668)

► CONSTANTINE VII PORPHYROGENITUS, 905–959 CE

Much of what we know about the Byzantine imperial court and government is due to the unusual career of the emperor Constantine VII Porphyrogenitus. Constantine was only six years old when he inherited the throne, so the empire was ruled by regents and coemperors. Until he was 39 Constantine remained in the background, while Romanus Lecapenus (921–945) ruled as a strong senior emperor for more than 20 years. He unexpectedly became the actual emperor in 945 and ruled for 14 more years.

Constantine spent his years in retirement in the imperial library reading and commissioning encyclopedic collections of knowledge preserved in ancient manuscripts. His goal was to preserve all the useful information from the ancient world for future emperors, from agriculture to veterinary medicine. His collection included an account of all the imperial ceremonies and a handbook of information about each of the foreign peoples the empire dealt with. Travelers who viewed the ceremonies left accounts of the awe they could inspire. Constantine also patronized an artistic revival of classical style, evident in manuscript illuminations and ivory carvings. As a scholar-emperor, Constantine represents the importance of ritual and learning that was unique to Byzantium in the medieval Christian world.

—Dorothy de F. Abrahamse

Byzantine gold solidus of Constantine VII, 945. Byzantine gold coins and Abbasid silver coins were the standard currency in the Mediterranean world and Europe in the early medieval age. (Barbara Heller)

even moved his government to Sicily for safety. Continuing religious strife, rebellions, and civil war deepened the crisis at the turn of the eighth century, and the end of Byzantium seemed inevitable. In two great sieges of Constantinople (674–678 and 717), the Arab caliphs attempted to complete their conquest of the empire. Constantinople's strong defenses, the use of Greek fire, and the imperial forces held the city and enabled the empire to survive, but Arab forces continued to attack Asia Minor. Emperor Leo III (r. 717–741) and his son Constantine V (r. 741–775) established a stable imperial dynasty and saved the empire. They were able to put in place military reforms, strengthen provincial administration, and mount a successful defense against Arab and Bulgar invaders, but their controversial policy of outlawing the use of icons left such hostile accounts in the sources for the period that it is difficult to appreciate their achievements.

Political crisis returned in the early ninth century when Empress Irene (r. 797–802) attempted to rule in her own right and restore icons and her successor was killed in a disastrous loss to the Bulgarian khan Krum. But the principle of dynastic rule became firmly established during the reign of the Amorian family (820–867) and the Macedonian dynasty, whose emperors ruled for two centuries (867–1056). Basil I (r. 867–888) became emperor by assassination, but five generations of his descendants held the throne. During the reigns of Constantine VII Porphyrogenitus (r. 913–959) and Basil II (r. 958–1025), the coemperors Romanos Lecapenus (r. 920–944), Nicephorus Phocas (r. 963–969), and John Tzimiskes (r. 969–976) were responsible for much of the empire's military success but could not displace the legitimate emperors.

The Macedonian period realized the creation of Byzantium as a powerful medieval state. Beginning in the reign of Michael III (r. 842–867), recovery was achieved through a long series of military campaigns against powerful neighboring states, the Bulgar kingdom in the Balkans, and Arab emirates in the east and south and through success in diplomacy and conversion. Byzantine missionaries converted the Bulgar king to Orthodox Christianity about 865, bringing Bulgaria into the cultural orbit of Byzantium.

Warfare, however, continued until Basil II finally conquered and incorporated Bulgaria into the empire in 1018. From the campaigns of Basil I (867–886) through the tenth century, Byzantium was able to take advantage of the disintegration of the Arab empire to consolidate the eastern frontier in Anatolia and reconquer former Byzantine territories. Nicephoros Phocas and John Tzimiskes led expeditions that restored Crete, Cyprus, and Antioch to the empire and extended its borders deep into Armenia. After the Kievan Rus made frightening raids on Constantinople, Byzantium bound them to the empire as allies in the tenth century and cemented their conversion to orthodoxy with the unprecedented marriage of Basil II's sister to the Russian prince Vladimir in 988. In 1025 the Byzantine empire was the dominant Mediterranean power.

Byzantine success in the ninth and tenth centuries was built on a strong imperial autocracy. The imperial government directly controlled the army and the provincial government, maintained a system of taxation, and paid salaries in gold to its administrators. The court sponsored the recovery of classical manuscripts and revival of late ancient learning. Emperors ruled in a restored capital unequalled in historic and ritual symbolism and surrounded themselves with ancient ceremonial that awed foreigners and citizens. It is not surprising that scholars often consider this period the apogee of Byzantium.

Rhomaioi—Who Were the Byzantines?

The empire and people we know as Byzantine never used that term to describe themselves.

Throughout its history the inhabitants of the empire called themselves *Rhomaioi*, the Greek term for Romans, and their ruler “emperor of the Romans.” The term “Byzantine” was a designation developed by the German humanist Hieronymus Wolf in the sixteenth century to differentiate medieval from ancient Greek texts. During the history of the empire the term “Rhomaioi” came to have different meanings and was the source of both contention and confusion with western rulers, but in Byzantium it encapsulated the Roman continuity and Christian identity of the eastern empire.

When Constantine I moved his capital to Constantinople, the “New Rome,” in 330 CE, he and his successors ruled a single multilingual and largely polytheistic empire, east and west, whose citizens were naturally “Romans.” During the fifth century as the empire became increasingly Christian and the west disintegrated, the term “Rhomaioi” described a subject of the Christian empire, as Greek became the lingua franca of the east for religion and government, and the use of Latin diminished. Pagan classical learning was suspect, and the word for Greeks, “Hellenes,” became a term of opprobrium that meant “pagan.” The sixth-century emperor Justinian (527–565) still used the traditional Latin title *imperator romanorum* as sole ruler of a temporarily restored empire, but in the early seventh century the Emperor Heraclius (617–641) adopted the Greek title “*Basileus ton rhomaion*.” The term “Rhomaioi” had no ethnic or national identity and included the inhabitants of all lands ruled formally or in reality by the emperors. In Justinian’s time it designated a largely eastern Mediterranean polyglot population of Greeks, Arabs, Copts, Syrians, and other ethnicities.

In the seventh and eighth centuries as Byzantium struggled to survive the onslaught of Arabs and Slavs, the term “Rhomaioi” came to signify the embattled defenders of Constantinople against Islam; by the ninth century it also reflected its orthodox identity. The empire that emerged in the ninth century emphasized its Roman-ness symbolically and substantively. Emperors elaborated ceremonial inherited from late antiquity, revived late Roman law, sponsored an effort to copy classical texts, and drew on them

for practices ranging from military tactics to medicine. The Middle Byzantine empire remained multiethnic, and the many individuals and groups it absorbed, notably Slavs, Caucasus tribes, Bulgars, and Armenians, were asked only to accept Christianity and imperial rule to become Rhomaioi. Administrators and educated citizens spoke and wrote Greek, but everyday life remained multilingual.

The identity of Byzantium as the Roman empire was accepted by most outside powers, from the Islamic rulers, who called it *Rūm*, to Kievan Russia and even early Frankish rulers in the west. The challenge to the Roman identity of the east came from the eighth-century Roman popes. Byzantine inability to protect Rome and Ravenna from invasion, compounded by Iconoclast beliefs considered heretical in Rome, led the popes to develop an elaborate defense of their own claim to be heirs of Rome and to seek new protectors in the Frankish rulers, whom they eventually sought to legitimate as rival emperors. Latin writers called Byzantines “*Graeci*,” a terminology that spread in the west, frequently with a list of derogatory modifiers carrying offensive connotations of paganism to Byzantines. By the eleventh century the Latin stereotype of devious, effeminate, and arrogant Greeks had displaced earlier, more positive interest in a related Roman world.

Although late Byzantine writers sometimes used the terms “*Graikoi*” and “Hellenes” in cultural contexts, they continued to identify themselves politically as Rhomaioi until the end of the empire, even when it had little hope of survival. The term remained powerful enough for the Russian tsars to claim their inheritance as the Third Rome after the fall of Constantinople in 1453.

The Merovingians and Carolingians

The ruling families of the Merovingian and Carolingian empires both descended from Frankish tribes. During late antiquity these tribes occupied territory in the lower Rhine River region and were divided into two groups: the Salian, or “saltwater,” and Ripuarian, or “riverine,” Franks. Sixth-century historian and bishop Gregory of Tours provides us with little detail on the origins of the Merovingian dynasty beyond its founding by the eponymous Merovech, purportedly of divine ancestry, perhaps in the early fifth century CE. Early Merovingian rulers were probably warrior chieftains raised to a higher status by acclamation and possibly tribal election. In the mid-fifth century Childeric seized lands in Roman Gaul, establishing Frankish influence as far as Brittany and the Loire.

The key figure in establishing Frankish dominance in much of western Europe, however, was Childeric’s son Chlodovacar or Clovis (later Louis, Ludwig) (r. 481–511). Clovis made expansion his

policy. He united the two main Frankish tribal halves and neutralized the potential rivals to the south and east. Without abandoning Austrasia Clovis led the Franks deep into Gaul, establishing a headquarters at Soisson. He married a Burgundian princess (Clothilda) who happened to be Catholic and was baptized Catholic in Rheims. While many Germanic groups remained polytheistic and others such as the Goths, Lombards, and Vandals subscribed to Arian Christianity, Clovis tied the Franks to the Catholic Church, its powerful bishops (such as Gregory), and Rome. Thus his Germanic political rivals became religious enemies as well, to be conquered and converted.

Clovis’s successors maintained strong ties of patronage and support for the Catholic Church, building and protecting churches and monasteries and encouraging conversion. In Frankish fashion at the ruler’s death the kingdom was divided among surviving sons, a tradition that naturally weakened both the Frankish territorial polity and the kingship. But the Merovingians were not beyond mutilation and even murder to eliminate rivals and reunite the kingdom under a single ruler, a feat accomplished by Dagobert I (r. alone 629–638). While Dagobert’s successors often ruled as very pious men, they were detached from active administration—especially in military matters—and earned the nickname “The Longhaired Kings.” Powerful nobles, especially those who served the kings as mayor of the palace in each major province, managed most royal affairs. In 732 the most famous of these mayors, Charles (Carolus), later named Martel (Hammer), defeated an army of Iberian Muslims near Tours in central France. The victory marked the end of Muslim encroachment in Francia and the ascent of the Carolingian family.

Charles’s son Pepin (also Pippin) the Short (r. 751–768) consolidated the mayoral positions in his own hands and later unseated the last Merovingian king, young Childeric III. Pepin acted with the support of a nobility that had tired of weak central rule and a pope who was in need of an ally against the Arian Lombards in central Italy. Anointed king in 751 by Boniface, the famed English missionary to the Saxons, Pepin and his two sons marched to the aid of Pope Stephen. After defeating the Lombards, Pepin granted their southern territories to the pope. This provided

▶ THE ANNALS OF LORSCH RECORD PEPIN’S CORONATION AS KING OF THE FRANKS

“750 [751]—In this year Pepin was named king of the Franks with the sanction of the pope, and in the city of Soissons he was anointed with the holy oil by the hands of Boniface, archbishop and martyr of blessed memory, and was raised to the throne after the custom of the Franks. But Childeric, who had the name of king, was shorn of his locks and sent into a monastery.

753—In this year pope Stephen came to Pepin at Kiersy, to urge him to defend the Roman church from the attacks of the Lombards.

754—And after Pope Stephen had received a promise from king Pepin that he would defend the Roman church, he anointed the king and his two sons, Charles and Carloman, with the holy oil.”

► POPE GREGORY THE GREAT, 590–604 CE

Pope Gregory the Great's 14-year pontificate, 590–604, witnessed the solidification and extension of papal authority throughout western Europe. In this difficult period in the city of Rome, Gregory assumed the responsibility of restoring public buildings and took charge of the defense of the city in addition to making administrative and pastoral reforms. These reforms laid the foundations for the traditions of the medieval papacy. Gregory asserted the role of the papacy as a major power broker in Italy and in that role negotiated with Byzantines, Franks, and Lombards. Although he remained a loyal subject of the emperor in Constantinople, Gregory recognized the importance of the western Germanic rulers. These important contacts led to increasingly close ties between Rome and the west over the next century and a half, culminating in the formal alliance of the Franks and popes in the eighth century.

Pope Gregory the Great (d. 604) was very important in aligning the Catholic Church and the rising Merovingian power in early medieval western Europe. (Alinari/Art Resource, NY)

the pontiff with resources for the defense and marked the establishment of the Papal States. At Pepin's death both Charles and Carloman inherited the greatly strengthened kingdom, which was reunited at Carloman's death three years later.

Charles, or Charlemagne (Charles the Great; r. 768–814), tirelessly campaigned against the polytheistic Saxons, the Lombards, the Muslims in Spain, and the Turkic Avars who had replaced the Huns in Hungary. He seized the treasure horde of the Avars, the Lombard crown, forcibly converted or slaughtered the Saxons, and suffered defeat in Spain. Charles sought to control and communicate with his nobles and Frankish clerics through traveling *missi dominici* (messengers of the lord). He strengthened and tried to make the Church uniform by patronizing bishops and monastic houses. Charles replaced various monastic practices with the Benedictine Rule, implemented Gregorian chant, and pro-

vided books for education and liturgy. Pope Leo rewarded his efforts and accomplishments by crowning him emperor in St. Peter's Basilica at Christmas in the year 800, the first to hold that office in the west in 324 years. Charles's Carolingian Renaissance, directed from his palace at Aix-la-Chapelle, was an attempt to revive important elements of classical Roman culture as a way of both celebrating the renewal (*renovatio*) of empire and creating a common culture.

Charles's grandson Louis the Pious (r. 814–840) ruled alone as Vikings, Magyars, and Muslims hammered the empire, prompting the decentralization of authority and power. At his death his three sons—Charles, Louis, and Lothair—fought over their inheritance, further weakening the Frankish world. This civil war permanently divided the empire and led to the evolution of distinctly French and German cultures.

Anglo-Saxon and Celtic Kingdoms

During the Anglo-Saxon period, which stretched from the Roman retreat from Britain in 410 CE until the Norman Conquest of 1066, the British Isles were governed by a complex and shifting set of small kingdoms. Present-day Ireland, Scotland, Wales, and England were all colonized by mainland Europeans expanding their horizons after the Ice Age, but these newly minted Britons diversified into recognizably different peoples by the early medieval period. However, these varied populations did not remain genetically or culturally isolated. They participated in cross-border alliances and marriages and were also subject to

incursions by continental peoples. Despite these potentially ambiguous lines of distinction among the early peoples of the British Isles, there are some quantifiable facts regarding the early political organization of the region.

Although Ireland was supposed to have had more than 100 small kingdoms as late as the fifth century, its larger political organization divided the island into five large provinces. The center of government was at Tara, the traditional seat of the high king of all Ireland, located in the central province of Meath. Surrounding Meath were the provinces of Ulster to the north, Connacht to the west, Leinster to the east, and Munster to the south, all home to the set of provincial sub-kings and petty kings under the high king's rule.

Like Ireland, early Scotland was also seen as composed of five provinces. Scotland was the home of a people known to the Romans generically as the Picts, and Pictland was their ancestral stronghold in the north and east of the country. Irish invaders from Ulster established the province of Dal Riata in the west, while Strathclyde to the southwest bordered the kingdom of the Anglo-Saxon Northumbrians, as did Lothian in the southeast. The western islands of present-day Scotland formed the province of the Hebrides, largely under the control of the seafaring Norwegians.

The early medieval political organization of the Anglo-Saxons was also divided between vari-

THE SHORT CAREER OF QUEEN JUDITH

The life of an Anglo-Saxon queen was not usually a celebrated one. Most of these women receive scant notice in the historical record if any at all. A notable exception is Judith, queen first to the West Saxon king Aethelwulf (r. 839–858) and then his son Aethelbald (r. 855–860). Daughter to the Frankish king Charles the Bald (r. 840–877), Judith was married to Aethelwulf in 856 at the tender age of 12. Aethelwulf married Judith in the hopes of cementing a relationship with her powerful father. One condition of this marriage was the anointing of Judith as queen, giving her role as queen a primacy that flew in the face of Anglo-Saxon tradition. However, it was an importance that was

ultimately accepted by the Anglo-Saxons. Judith even held enough power to witness royal charters as queen. When Aethelwulf died in 858, the 14-year-old widow retained her queenly status. This power and her family connections made her an attractive marriage prospect for her stepson Aethelbald, who had inherited half his father's kingdom. They married, amid no little controversy, and Judith remained queen of the West Saxons until Aethelbald died two years later. Twice the widow by the age of 16, the inimitable Judith returned to her father's kingdom of West Francia only to elope against her father's wishes.

—Todd Preston

ous subkingdoms. In the case of the Anglo-Saxons, these kingdoms were known as the Heptarchy. Although a relatively simplistic concept forwarded by Venerable Bede (673?–735), the term “heptarchy” is useful insofar as it outlines the general political divisions among the Anglo-Saxons. Bede, in his *Ecclesiastical History of the English People* (731), describes seven subkingdoms of the Anglo-Saxons: Northumbria in the north, Mercia in the midlands, East Anglia and Essex in the east, Wessex in the southwest, Sussex in the south, and Kent in the southeast.

These subkingdoms battled for dominance among one another but also contended with Celtic and Scandinavian invaders. Eventually the kingdom of Wessex emerged as dominant under the rule of Egberht (r. 802–839). His descendants would eventually rule all of Anglo-Saxon England. King Alfred (r. 871–899) would accept the submission of the various Welsh kingdoms by the mid-880s, and King Aethelstan (r. 924–939) would solidify his hold on Northumbria to make him the first king of the English in 927. Thus the pattern of political consolidation in the early Middle Ages began the process of shaping the British Isles into the configuration we know today.

State Formation in Northern and Eastern Europe

The ninth and tenth centuries were a time of gradual creation of the medieval states in northern and central Europe and in the Balkans, which was quite substantially related to the external

pressure of powerful neighbors and to the spreading of Christianity. These two factors helped the creation of the new Europe in areas toward the north and northeast of the original area of the Roman empire and the incorporation of this region to the West European cultural sphere. These areas, a periphery of the Carolingian empire, had similar development through the Middle Ages, be it cultural or political (better preservation of old tribal legends or the development of political institutions).

The period until 1000 in the north is traditionally labeled as the Viking Age. It was the time of the first formation of power centers in the north as well as the development of the Baltic and the North Sea trade. The Vikings, being experienced navigators, not only administered this trade but also expanded through the sea: it was the time of devastating raids especially in western Europe and active searching for new lands of the north-erners. Central and southeastern Europe were populated by western and southern Slavic tribes; during the time of the Slavic expansion they settled as far west as the Elbe, coming into contact with the Frankish empire, and as far as modern Greece in the south, coming into contact with Byzantium. In the end of the ninth century a new element was brought by the Magyars and their settlement in Pannonia during the tenth century.

The first area of where states started to develop was the old territory of the Roman empire. There were the Avars, who created a statelike formation in the Danube basin. Their state significantly influenced the development of central Europe. Toward the south, however, the Turkish Bulgarians (who gradually became a Slavic nation due to the assimilation with the local Slavic

Messengers of the Moravian prince Rastislav ask Emperor Michael III to send missionaries speaking a Slav language; he sends to Saloniki for Cyril and Methodius. From the Radziwiłł Chronicle, late fifteenth century. During the early medieval period, the pagan rulers of northern and eastern European peoples converted to either Catholicism or Orthodox Christianity as part of the state formation process. By doing this, it was thought the new states would acquire divine protection. (Erich Lessing/Art Resource, NY)

SAINTS AND STATES

Christianity meant, for the early states, not only bringing of culture but usually also a legitimization of the ruling dynasty. The members of the ruling dynasty could become bishops of the local church, but in a few cases it happened that a member of the ruling dynasty became a saint whose cult and veneration then helped the propagation of the family. In the tenth century it was St. Wenceslas (d. 935), who after being murdered by his own brother became a national saint of Bohemia. Prince Vladimir of Kiev, who commanded the conversion of Russia to Orthodox Christianity in 989, has also been elevated to sainthood. In the early eleventh century there are examples of Norway with St. Olaf Haraldsson (d. 1030) and Hungary with St. Stephen (d. 1038). These men were crucial in spreading Christianity and consolidating the power of their states. Later on, but relatively soon, they became symbols of their states themselves: national saints.

—Antonin Kalous

population) created a state independent of Byzantium as well as the Avars. Traditionally the year of the creation of the state is 680, but it was only at the beginning of the ninth century when the state was more consolidated under Khan Krum. The constant conflicts with Byzantium made the administration necessary. And this model repeated in other areas.

In the north it was Denmark, which was the first to come into contact with the Carolingian empire. Charlemagne's war against the Saxons meant that the Frankish expansion reached the borders of the Danish lands. Charlemagne endangered the Danes also by promoting a coalition with the Obodrites (Polabian or Elbe River Slavs), which was the first of these Slavic peoples to have some more significant power centers. They were allies of the Franks but later also cooperated with the Danes. The Frankish king also helped the consolidation of the Slavic tribes in central Europe. First, he defeated the Avars (but did not integrate the territory into his empire) and thus enabled the local tribes to proceed in their own state formation. Second, by his own intrusion to the territory of Bohemia, he

compelled them to pay a tribute (similarly as other bordering Slavic tribes). In the peripheral areas of the old Avar territory Slavic states started to develop in the eighth century, the most important of them being the states of the Carinthians and Moravians. After the fall of the Avars (795–804), thanks to Charlemagne and Krum, the new states were able to acquire larger territories and powers.

Not only the military pressure of the powerful neighbors but also Christianization of this region stimulated the creation of the new states. In the ninth century the Moravians and Czechs in central Europe learned about Christianity, and the Moravian ruler Mojmir was baptized in 834. Bulgaria had already become Christian in the 860s. The Carinthians and Croats were exposed to missions earlier since they were living in the originally Christian areas. The north was, like central Europe, a new ground for Christianity. The most activity can be attributed to St. Ansgar (who made several missions among the Danes and Swedes in the 820s–860s) and his followers on the Archbishopric See in Hamburg-Bremen. In the tenth century the Poles and the Hungarians accepted Christianity.

For these new states Christianity and the Church administration was of crucial importance, for it not only gave the state (and the dynasty) a new ideology and legitimacy but also created a powerful tool of the state administration. Through the individual archbishoprics (i.e., by creating the local church), which were always desired by the local rulers, the states were also able to become more independent of their powerful neighbors. The case of Great Moravia is quite illustrative: Rastislav (r. 846–870) wanted to have an independent church, and even though the land was frequented by missionaries from Bavaria (then a part of the Frankish empire), he asked the pope for missionaries directly from Rome. When Rastislav did not get them he asked for the same from Constantinople, whence brothers Constantine-Cyril and Methodios came to Moravia. They brought a new script for the Slavic language and created a church based on Old Church Slavonic as the liturgical language with its independent archbishopric. Later on, however, their disciples were expelled, and the Latin liturgy took the ground.

In the period until 1000 many new states developed in northern, central, and eastern Europe. By accepting Christianity (mostly from the West except for Bulgaria and Russia) they became a part of European culture and tradition. Even the Magyars, who are first described as total strangers both to Christianity and to European culture, were gradually incorporated in the community of the Christian states. Thus most of the nations of Europe became Christians (at least nominally) by the eleventh century. Only the areas of Polabian Slavs and the Baltic peoples remained heathen for a few more centuries. We can also say that most of the states that were created in the tenth century survived for a long time (unlike their predecessors) and form the image of Europe even today.

Early Kievan Rus, 860–1000

Kievan Rus was a state that emerged on the banks of the Middle Dnieper River toward the end of the ninth century. Kievan Rus is usually considered the forerunner of the modern states of Russia, Belarus, and Ukraine. The appearance of Kievan Rus marked a major milestone in the history of Inner Eurasia: the beginning of a transition from migratory pastoralism to sedentary agriculture, a process that would sweep Inner Eurasia from the European plain to the Pacific Ocean.

The spread of sedentary agriculture out of east-central Europe started in the sixth century CE with the expansion of the Slavic peoples from their homelands north and east of the Carpathians, an expansion that may have been a response to increasing populations resulting from improved agricultural technology and crops. Some moved west to the Vistula and the Elbe, others migrated to the Balkans, while still others moved east to the Volkhov River and especially the fertile lands of the Middle Dnieper.

After the establishment of the Khazar empire in the seventh century and the security against pastoral raiders that this provided, agricultural villages began to be established by Alans and Sabirs as well as Slavs on the northern edge of the steppe.

With the growth of settlements came an increase in population and wealth, tempting marks for marauders seeking booty and slaves. In the early centuries of this Slavic expansion, the Khazar empire collected tribute from many of these villages, but it also offered some protection against the pillaging of pastoral nomads. To collect tribute, the Khazars built stone fortresses, such as Sarkel on the Don, and garrisoned strong points including, importantly, Kiev.

The Khazars collected tribute in forest products, furs, honey, beeswax, and slaves, which they sold to the Muslim caliphates for silver. Scandinavian Vikings, who had already developed a trade with the Finns and Baltic peoples east of the Baltic Sea, began to penetrate the rivers of western Russia to get to the source of the silver. They built strong points at Staraia Ladoga and Gorodische on the Volkhov River and at Timerevo and Sarski Fort on the headwaters of the Volga. From these strong points, they launched marauding expeditions to gather plunder and slaves to trade with the Abbasid caliphate as well as with the Volga Bulgars and the Khazars. Success attracted more Viking adventurers from Scandinavia, and they fanned out over the forests, demanding more tribute and slaves.

Although these Viking freebooters were a turbulent lot, in 850 they were loosely confederated in the Khaganate of Rus, whose dates probably were 850 to 940. The Khaganate, with its armies of Slavic, Finnic, and Balt tribesmen as well as large contingents of Viking berserkers,

Olga, widow of Igor, prince of Kiev, has the envoys of the Drevlyans buried alive after their arrival by boat. Igor was killed in battle against the Drevlyan prince in 945 CE. From the Radziwill Chronicle, late fifteenth century. (Erich Lessing/Art Resource, NY)

was very powerful. In the beginning, its capital was at Gorodische, but perhaps at the onset of the tenth century a new capital, Novgorod (“New Town”) was constructed next to the old Viking strong point. The Khaganate, a brutal slaving mafia, sent great fleets down the Volga to the shores of the Caspian Sea to trade in amber, European swords, and slaves or to pillage the Muslim villages on the shore of the Caspian. The Rus, either under the auspices of the Khaganate or in independent bands, also sent fleets into the Black Sea that ravaged the coasts of that sea and twice mounted unsuccessful attacks against Constantinople.

By 900, Viking interest was gravitating toward the Kiev region. Kiev was an old settlement, predating the Slavic expansion. By 900, it was the heart of a very rich and heavily settled agricul-

tural area, perhaps one of the most productive in eastern Europe. It was on the periphery of Khazar power, but the Khazars probably kept a garrison there until late in the ninth century. The Russian *Primary Chronicle*, notoriously unreliable in its early chronology, states that Oleg, a mercenary in the service of the Rurikid dynasty of Novgorod, conquered Kiev from Dir and Askold, who may have been previous Viking conquerors. However, the first Kievan prince of the Rurikid dynasty with solid historical certification was Igor, who reigned in the 940s.

In Kiev, princes of the Rurikid dynasty established a kingdom that was an uneasy union of city-states all ruled by members of the dynasty of Rurik. Supported by powerful armies composed of Slavic and Finnic troops but whose elite forces were composed of the Viking mercenaries, the new state supported itself with tributes collected from the quasi-independent Slavic groups inhabiting this rich agricultural region.

Kiev under the Rurikids soon embroiled the region in war. Kievan armies battled the Byzantine empire, the Bulgars of the Danube, the Volga Bulgars, the Pechenegs, and the Khazars as well as the Slavic tribes who dwelt as far away as the Oka River area, near present-day Moscow. Igor led an army in an unsuccessful campaign on the Byzantine empire. In 945, he attacked the Drevlyans, a Slavic tribe who were becoming increasingly reluctant to satisfy Igor’s demands for tribute. The Drevlyan leader, Mal, defeated Igor and killed him. This action did not go unpunished, because Igor’s wife, Princess Olga, who ruled as regent for her underage son, Svyatoslav, led armies that exacted brutal revenge.

Olga’s policy toward Byzantium was more pacific. She negotiated with the Byzantine emperor and even journeyed to Constantinople and converted to Christianity.

Her son, Svyatoslav, remained a staunch polytheist. When he reached maturity, he led armies against most of his neighbors. He destroyed the Khazar empire and sacked its capital, Itil, as well as the Khazar stronghold of Sarkel on the Don. In 968, he joined with the Byzantines to attack the Bulgarian kingdom. The wealth of the Danubian region impressed Svyatoslav, and he decided to establish a new capital

there. The Byzantine emperor, John Tzimisces, alarmed at the prospect of a new neighbor more powerful than the Bulgarians, negotiated with the Pechenegs to attack Svyatoslav's army. The Pechenegs destroyed the Kievan Army as it was crossing the Dnieper and killed Svyatoslav. The Pecheneg leader and his family used Svyatoslav's gilded skull as a cup from which to drink toasts on ceremonial occasions.

On Svyatoslav's death, his sons launched a nine-year war of succession. The youngest son, Vladimir, prince of Novgorod, won the struggle when he recruited fresh levies of Scandinavian mercenaries and seized Kiev in 980. Vladimir's reign lasted 25 years and was a turning point in the history of Kievan Rus because it was during his reign that the prince and the people converted to Orthodox Christianity.

Vladimir, who appreciated the utility of a state religion in conferring legitimacy on the government, at first turned to the Rus blend of Slavic, Scandinavian, and Iranian paganism in order to cloak his regime in legitimacy. He erected monuments to pagan gods and seemed intent on strengthening the role of traditional priests in Kiev. But in a sudden about-face in 899, Vladimir ordered the conversion of his state to Christianity.

The twelfth-century monks who composed the *Primary Chronicle* relate, in a charming but probably apocryphal tale, that Vladimir's search for a religion was the result of a studied comparison of the practices of Jews, Muslims, Catholics, and Orthodox Christians, but it probably was influenced as much or more by strategic and economic considerations. Byzantine emperor Basil II engaged in his epic conflict with the Bulgarian kingdom as well as revolts in Asia Minor and sought a military alliance with Vladimir. Vladimir's price was high: Basil's sister, Anna, must be given in marriage to Vladimir. Basil apparently agreed but was slow in sending Anna to Kiev. Only after Vladimir's forces attacked the Byzantine Crimean city of Cherson did Basil send his sister to Vladimir.

Along with Anna came Orthodox priests and all the panoply of the Orthodox Church. The great statue of the pagan god Perun that Vladimir had erected on the banks of the Dnieper was thrown down, and the people of Kiev were

baptized en masse in the river. The conversion to Orthodoxy meant that Kievan Rus would become part of the zone of Orthodox civilization at a time when the divergence between Latin Western Christianity and Greek Eastern Christianity was becoming wider.

Vladimir was named a saint in the Russian Orthodox Church, and Kievan Rus began its career as the expanding eastern wing of Christendom. Kievan Rus would endure until 1240, when the Mongols sacked and burned Kiev.

Georgian Kingdoms

Politically, Georgia in the year 300 did not exist. The land that would 700 years later become Sakartvelo (“the land of the Kartvels”), or what we in the West call “Georgia,” was made up of several kingdoms divided into two cultural and political zones. Eastern Georgia, composed principally of the region of Kartli, or Iberia, was exposed to Persian influences but had managed to retain its formal independence. Western Georgia, straddling the Black Sea, comprised Colchis (also known as Egrisi, or Lazica) and had fallen under the sway of Rome.

This was the setting, in about 337, for the conversion of King Mirian of Kartli to Christianity by St. Nino, a humble woman from Cappadocia (present-day Turkey). Though archaeological evidence shows that early followers of Christianity had been present in western Georgia by the year 200, formal adoption of the new religion did not take place until about the same time as Kartli. For Georgia, conversion to Christianity was a pivotal moment. For the first time in its history, the country looked toward the West.

Though Georgia now oriented itself to the West, it faced a stern challenge from the East. In 363 Persia, reenergized by a new dynasty, the Sassanians, defeated Rome and asserted its political hegemony over Kartli. Toward the end of the 400s, Vaktang Gorgasali, king of Kartli, waged a vigorous struggle against Persia but ultimately was defeated. However, one significant achievement of Gorgasali's reign would have lasting repercussions: the establishment of an autocephalous (that is, independent) Georgian church. Despite the political setbacks of this time, the institutional basis for a cohesive Georgian identity had been set.

Kartli's political decline continued after Gorgasali's death. By 520 the authority of the monarchy had been substantially diminished, and by the 580s it was abolished outright by the Sassanians. A similar process of political subjugation was ongoing in western Georgia, with Byzantium increasingly asserting military and political control over Colchis/Lazica.

It is important to note that until the seventh century Georgia, along with its neighbor Armenia, was monophysite, that is, it held the doctrine of the one and single nature of Christ. This conflicted with the teachings promulgated by the imperial church council of Chalcedon in 451. But in 607, at a time when Georgia increasingly looked to the Byzantine empire for protection from Sassanid Persia, Georgia broke with the Armenians and embraced diophysitism (the doctrine that holds that Christ's nature is both wholly human and wholly divine). Once again, Georgia looked to the West.

Georgia's growing links with Constantinople were temporarily disrupted in 645 when Arab armies, fervent with the zeal of a new religion, Islam, invaded. By 655 all of Kartli had become an Arab emirate. Though the emirs interfered little with Georgian culture, Muslim suzerainty caused many Kartlian nobles and religious elites to relocate to the southwest, to the regions of Tao-Klarjeti and Shavsheti, far from the Arab metropole based in Tbilisi (founded by Vaktang Gorgasali in the fifth century). Unimpeded access to Byzantine ideas and practices led to a great cultural efflorescence in this "neo Kartli." Important new churches were founded, the size and scale of which exceeded anything being built in Byzantium at that time, while a great

output of religious literature—gospels, exegetical works, philosophical tracts—testify to Georgia's increasing cosmopolitan outlook.

Western Georgia was untouched by the Arab invasions, and in 795—at the same time as "neo Kartli" was being created by a diaspora community in Tao-Klarjeti and Shavsheti—Leo III, king of Abkhazeti (far northwestern Georgia), brought all of Colchis/Lazica under his dominion, with Kutaisi as the capital. It was during this period that the church in western Georgia broke off from the patriarchate in Constantinople, to which it had formerly owed allegiance, and subordinated itself to the church in Kartli. The Western and Eastern churches in Georgia were now united. The stage was set for political unification.

As a sense of national identity emerged, two of the first histories were composed sometime in the ninth or tenth century, both dealing with the spread of Georgian Christianity: *The Conversion of Kartli* and its more elaborate counterpart, *The Life of St. Nino* (earlier redactions can be traced to the seventh century). Though these histories are concerned with events from the fourth century, their outlook reflects a growing sense of nationhood and the desire to construct a Georgian past.

A pivotal moment came in 813 when Ashot I, from the Bagratid family, seized political control of neo Kartli. Unification now became an overt political goal, impelled in part by a common struggle against outside forces and the increasing idea that Georgians, both east and west, shared a common culture and inhabited a single land, Sakartvelo. After much difficulty, in 1008 the kingdoms of Kartli/Iberia and Abkhazeti were unified by Bagratid III. The next two centuries would be a golden age for Georgia.

■ Introduction: Political Change in the Americas

In the Americas during this era, political structures ranged from the informal politics of the small hunting and gathering band as existed among the dwellers of the Arctic or the extreme southern tip of South America to the institutionalized states of Mesoamerica and the Andean region. Because we understand little about the communication systems of these peoples (except for the writing of the Classic Period Maya), most of what historians can say about political structures of the Americas and changes in them in this age is derived from inferences based on artifactual evidence.

It is conjectured that in the more sparsely populated regions where some type of agriculture was possible, independent villages were the rule. In more densely settled areas, where resources were more abundant, chieftaincies, groups of villages ruled by one chief or headman, were common. This was the case of the Mound Builder villages of the Mississippi Valley, the North American southeastern region, the Pueblo farmers of the North American southwestern region, the salmon and marine mammal hunting villagers of the North American Pacific coast, the acorn-eating villages of California, the farming villages of the Amazon Basin, and the circum Caribbean peoples of the West Indies, northern South America, and Central America.

It was only in the more densely populated and intensively farmed regions of Mesoamerica and the Andes that what we would recognize as states appeared. These states were usually small by modern standards, often little more than city-states, including only a city and its hinterland. However, in a few cases, larger entities emerged.

Such is the case of Teotihuacan, which was the largest city in the Americas and among the larger cities in the world in the middle of the first millennium CE. From about 100 to 500 CE, Teotihuacan was the hegemon of Mesoamerica, dominating the region commercially, culturally, and to some extent politically. Evidently, Teotihuacan not only exerted cultural influence over the Maya cities to the southeast but also held some of the Maya cities in a sort of imperial con-

trol. Teotihuacan's influence ended in the fifth century when the great city was mysteriously destroyed and the population scattered.

Historians know more about the Maya city-states. They flourished during the Mayan Classic Period, from about 200 to 900 CE. There were many Mayan city-states, each independent or striving to be, and each ruled by its own king or, occasionally, queen. Maya royalty was believed to intercede with the gods for divine favor for their city. Warfare among the cities was frequent and very bloody. For much of the period, the Maya cities coalesced into two alliances, one centering on Tikal and the other led by Calakmul. The struggle between these two cities, reminiscent of the struggle between the ancient Greek cities of Athens and Sparta, lasted much longer than the Peloponnesian Wars but, like the Greek conflict, was inconclusive, with losers but no winners. Although the Maya made great achievements in mathematics and astronomy, in politics and statecraft they ended about where they began. The Maya Classic Period ended with massive droughts and savage famines in the ninth century.

We know much less about the states of the Andean region than we do about those of Mesoamerica. The Andean peoples may have had a method of recording their thoughts in the system of quipos, knotted chords in which the knots are read according to their size and technique, or the quipu may have been simply mnemonic devices to keep numerical records. Unfortunately, we will not know until and unless someone discovers how to read the quipu.

Archaeological evidence indicates that three or four Andean peoples had states in this period: the Moche, the Nazca, the Tiwanaku, and the Wari. The Moche lived in northwestern Peru, farming the short valleys of rivers that rushed down the west slope of the mountains to the Pacific Ocean. They probably had several states, each in its own valley. We can conjecture, from the rich grave goods excavated from the tomb of the Lord of Sipan, that their rulers were very powerful and revered by their subjects.

We can know more about Tiwanaku. Tiwanaku was a city built in the wetlands on the shore of Lake Titicaca. The people of Tiwanaku had developed an extremely productive agricultural system and an elaborate civilization. To gather resources from different ecological zones, the Tiwanaku sent out colonies to remote places to grow maize, tropical fruits, cotton, and other exotic products. Their state resembled an archipelago of settlements and control. Little is said about their form of government except that it seems to have been based on a very powerful and privileged ruling class.

Wari was a territorial empire, a precursor of the Inca empire that would, centuries after the demise of the Wari, occupy the same territory. The people of Wari used quipu and, like the Inca, built roads to connect their strong points. Both the Wari and Tiwanaku declined precipitously in the great droughts that afflicted the region in the tenth century CE.

Stateless Villages in Most of the Americas

In most of the Americas between 300 and 1000 CE, the most common type of human polities were stateless villages. These settlements represented a milestone on the path to more complex societies for some groups, while other villages were the culmination of social development for others. These villages also were a stepping stone from egalitarian societies to highly organized and hierarchical societies in which individuals and groups held status because of their birth.

Unlike rulers of states, chiefs of villages have limits to their power. They lack a bureaucracy and institutions that reinforce their power. While both types of rulers may combine religious and political power to maintain their positions, chiefs operated with limits. Their people submitted to their power in both religious and secular matters, but the organization remained based on a voluntary exchange of services. While villages developed a hierarchical and stratified society, the chiefs remained answerable to those they led.

Villages developed as bands of humans became more sedentary and less nomadic. The

beginning of agriculture encouraged this development, as humans were able to depend upon a steady supply of staple crops. The adoption of maize as the mainstay of a group's diet is the most common example. However, many groups that did not grow maize adopted a sedentary lifestyle during this time. They continued to depend upon hunting and gathering of wild plants for their sustenance. Certain areas, such as the eastern woodlands in the future United States, provided sufficient game and plants to support this type of life. Other villages, such as those in Florida or the Pacific Northwest, depended upon marine life for most of their food. The availability of dependable sources of food resulted in increased population.

As villages grew, a change in the society followed. While most nomadic peoples followed leaders because of their personal qualities and knowledge, village life encouraged the change from an egalitarian to a hierarchical society. Nomadic groups tended to follow leaders who had displayed leadership qualities and knowledge about their environment and the group's traditions, and villages slowly evolved to put leadership in the hands of particular families or groups, based upon their birth. Decisions were made less often by consensus and more often by individuals. The power of these chiefs increased as they oversaw more and more aspects of village life, ranging from trade with other groups to warfare to protect the resources controlled by the village.

Because stateless villages did not have formal social structures, such as a bureaucracy or legal codes, hierarchical leaders reinforced their special position through religious means. Chiefs played a central role in mediating between the people and the gods. The gods' favor was necessary for the group's success. Different groups throughout the Americas had different theological beliefs, but each group was influenced to some extent by contact with others. The Southern Cult, for example, included motifs of death and deities. Artifacts with Southern Cult symbols, such as hands with eyes gazing out, have been found from Florida to Texas and into the Great Lakes region. Chiefs assumed a leading role in religious rituals. Ceremonial centers developed that sometimes served a network of vil-

lages. One example would be the Mississippian culture, based upon the floodplains of the Mississippi and Missouri as well as other tributary rivers. Ceremonial centers, such as Cahokia, were surrounded by villages and homesteads. Flat-topped mounds, topped with ceremonial buildings, were central to the Mississippian culture's religious practices. Chiefs performed rituals on these mounds that were sometimes observed by the ordinary people. Eventually, chiefs in many cultures were worshipped as deities because of their intermediary role.

As chiefs' political and religious power grew, they were more able to mobilize the village's workforce on community projects. Ceremonial mounds, protective stockades, irrigation projects, and similar works were supervised by the chiefs or their assistants. These ceremonial centers usually marked the center of a territory associated with a particular political entity. While individual villages had their own chiefs, each was subordinate to a hierarchical superior. The pattern is associated with peoples as diverse as the Arawak villages in the Caribbean and the Pueblo settlements in the American Southwest. Individual villages remained largely autonomous, but the inhabitants of the associated settlements considered themselves related to the larger group through either family connections, language, or heritage.

The villages maintained trading contacts with distant people. Specialists within the village made goods that were wanted by other groups. Trade goods included desirable materials for tools, weapons, or prestige goods. Examples of materials that villages in the Mississippi area traded included obsidian from the Southwest, copper from the Great Lakes or Appalachians, mica from the Southeast, and shells and sharks' teeth from the Gulf of Mexico. Control over the distribution of these prestige goods was in the hands of the chiefs. In the stratified society, the upper ranks possessed most of the goods. The use and display of the goods marked an individual's place in village society. Large amounts of prestige goods have been found in graves all across the Americas. The amount of goods indicates the social standing of the person buried. Chiefs and members of the ruling families have large amounts, while ordi-

➤ ANASAZI CLIFF DWELLINGS

Like other stateless villages, the inhabitants of this pueblo were dependent upon their own resources for constructing, maintaining, and defending their dwellings. Cooperation and consensus among the people was vital to the village's survival. The pueblos, located on cliffs and with few exterior openings, were well designed to keep out intruders.

nary individuals have far fewer possessions buried with them.

Chieftainships—Mound Builders and Pueblos, Amazonia and the Circum-Caribbean

Chieftainship is an intermediate stage in political development between a tribe and a state. The chieftainship is normally inherited, but the

position of the chief may be unstable and insecure. Chieftainships do not have the institutionalized methods of control that a state has. Many chiefs rely on asserting their authority through demonstrations of spiritual power and backing, through conspicuous consumption, or through large-scale building projects.

In pre-Columbian America, chieftainships developed between 300 and 1000 CE in a number of areas outside Mesoamerica. These areas included the Mississippi Valley where Mound Builders created monuments, the American Southwest where groups of Native Americans worked together to create defensible pueblos, and the Amazon region and the shores around

the Caribbean where fewer enduring examples of chiefly authority have survived.

Societies at a less complex level of development rely on leadership by individuals who have proven their abilities, whether through military prowess, speaking ability, or outstanding achievements in other areas. Their authority is limited and may be restricted to an area in which they have demonstrated their abilities. Population densities in these societies are normally low. Although the various groups in a tribe feel a kinship, they only cooperate in unusual circumstances and retain a great deal of autonomy.

The development of chiefs in a society is often indicated by the presence of exotic goods

Mississippian shell gorget, about 1000 CE. The gorget depicts crested woodpeckers, symbols of war to the Mississippians, guarding the four directions that encircle the sun. (Barbara Heller)

buried with infants or children too young to have distinguished themselves. The presence of such goods indicates that these children were born into a family of elite status. Chieftainships probably developed when the leader of one settlement convinced his people to gain control over neighboring settlements. Many times, conquered people were integrated into the home settlement of the chief, allowing for greater control.

In the chieftaincies, the position of the chief depended on him convincing his people that he was favored by the gods and shared in divine power. Several methods were apparently used. One was to require labor on complex building projects for ceremonial purposes. The mounds in the Mississippi Valley were created by Mound Builders for religious rituals and displays sponsored by the group's chiefs. These constructions were demonstrations of his authority. The roads constructed in the Chaco Canyon area were apparently built for similar religious reasons.

Another method of emphasizing the favored status of the chief and his family was their exclusive right to wear and use exotic goods. Examples of these goods were buried with the rulers, allowing archaeologists to identify the elites. These goods were usually rare or imported articles obtained from great distances or through

difficulty. Among the Mound Builders, examples of such goods included shells from the Gulf of Mexico, jade from Mesoamerica, and copper items from the Great Lakes region. Extensive trade routes brought these products to the elite consumers but not to the ordinary people.

The failure of a chief to protect and provide for his people could lead to his downfall. If he claimed authority because of divine favor, his failures could indicate that he had lost that blessing. In all four of the regions, the chieftainships failed to develop into more complex states, thanks to environmental and other causes.

Farming Cultures in North American Southwest

What archaeologists call the Mogollon Culture emerged sometime between 200 BCE and 200 CE along the Mogollon Rim's desert and forested highlands of southern Arizona and northern Mexico, and then it disappeared. According to Emil W. Haury, the Mogollon resurfaced as part of the Anasazi around 850. From archaeological evidence, the Mogollon people relied on rainfall and not on irrigation to obtain sustenance from their fields.

It is nevertheless the settlements of the Mogollon Culture found in the colder, wetter, and more mountainous reaches of east-central Arizona as well as west-central New Mexico that have received the most scrutiny by archaeologists. The Mogollon peoples lived at first in small villages consisting of pit dwellings. These early pueblos normally had fewer than a dozen rooms where perhaps one or two extended families resided. The Mogollon evolution is characterized by five stages, the last ending about 500

► CHACO CANYON—THE DEBATE GOES ON

Pueblo Bonito, which many archaeologists see as the capital of the Chaco Experience, was clearly a very important ceremonial center. Wolcott Toll has emphasized (and many other scholars have accepted his notion) that in order to understand Chacoan society, one must pay attention to the commonalities of modern-day Pueblo ceremonies. Pueblan society, like that of its historic past, is conditioned by the changing seasons. Corn consequently was a central aspect of Chaco society, as it is with the present-day Pueblos. We may surmise also that the rituals practiced by modern Pueblo Indians were similar or perhaps identical to those at the height of the Chaco Canyon era. In terms of the structuring of the so-called Chaco State (if this latter delineation is accepted), it is hard to unravel the pattern of office holding. Were positions hereditary? We really do not know for certain. However, the recent work of Brian Fagan (2005) offers a thorough review of the

archaeologists who have studied and continue to argue about the Chacoan political structure. He has noted that the only indication about the possible power of Chaco Canyon's political leaders emanates from Pueblo Bonito (particularly in light of research of excavated burial sites there). David Wilcox "believes Chaco was a small state administered from Pueblo Bonito, with territorial chiefs living in outlying communities." Fagan, on the other hand, embraces Frank Cushing's much-maligned notion of a council of priests representing the six cardinal points. Fagan's and Cushing's championing of the so-called Masters of the Great House as the real model of the system of governance for Chaco Canyon's Pueblo Bonito remains a subject for speculation and argument. The accuracy of this view depends on whether the structure for the later Zuñi was actually a continuation of that followed by the Chacoans.

—John S. Leiby

years ago, and six regional variants. As time progressed Mogollon communities became ever larger so that by the time of Columbus they possessed pueblos that perhaps numbered several hundred rooms. This latter process would mean a more stratified hierarchical society and also a much more developed division of labor.

The Anasazi—"enemy ancestors" in the Navajo language (although denoted by scholars as the "ancient ones")—inhabited the plateau region of the present-day American Southwest. Many tourists each year visit the elaborate cliff dwellings found in Mesa Verde National Park, Navajo National Park, and Canyon de Chelly National Monument and the Great Houses of Chaco Culture National Historical Park.

Before 500 CE the Anasazi Basketmakers, so named because of their intricately woven and decorated baskets, settled in caves and rock overhangs—cliff dwellings—near streams or rivers. They located themselves along these canyon walls facing south to take advantage of the warmth of the sun during the winter months. However, like the Mogollon and Hohokam peoples, the early Basketmakers built small semisedentary villages in open areas.

For clothing the Anasazi Basketmakers wore fur or turkey-feather robes, string aprons, loin-cloths, and plant-fiber sandals. They subsisted primarily on corn, beans, and squash, which they grew in small garden plots as compared to the large-scale fields found in the later Anasazi pueblos. They augmented their diet through hunting (mountain sheep, elk, mule deer, and black bear) and food gathering. Women, for instance, harvested wild crops such as amaranth, pinyon nuts, Indian rice grass, and sunflower seeds. The Anasazi Basketmakers were unaware of how to make pottery but were very adept at producing very ornate and sturdy baskets. Women cooked using these baskets by lining them with pitch. The food mixture and then fire-hot stones were added.

These baskets were fashioned into a wide assortment of sizes and shapes. They were utilized not only to transport possessions, for meal preparation, and for burial offerings but also to convey seeds and flour as well as to store grain and ceremonial items. To date, most early Basketmaker artifacts (mainly baskets) have been found by archaeologists within dry caves and rock shelters. The Anasazi Basketmakers' pace of evolution intensified by the middle of the first

millennium. This is evidenced by the construction of larger villages that possessed large storage and ceremonial structures. Some of the villages excavated by archaeologists in central New Mexico contain pit houses comprising more than 50 in number. Although the later Basketmakers continued to hunt and gather food, they increasingly devoted more time to the cultivation of domesticated crops and their ceremonial structures. Like the later pueblo peoples, the Basketmakers began to build *kivas* that contained a *sipapui*, or small entrance, where they believed the first people emerged from the underworld onto the surface of the earth.

While the Basketmakers' evolution lagged behind their southern counterparts, the pace of development hastened by the midpoint of the first millennium. They began to construct larger villages (with far greater storage capacity), signifying increased crop yields. For instance, in west-central New Mexico archaeologists have unearthed a number of villages whose extent indicates a much higher population in the regions inhabited by the Basketmakers. Accordingly, these larger villages led to greater social stratification and more power in the hands of the elites. Whereas the early Basketmakers had formulated an egalitarian society, increasingly the inhabitants of the ancient Four Corners region of the American Southwest evolved into a much more hierarchical society although not on the scale that arose in Chaco Canyon.

As time progressed the inhabitants of what today is called the Four Corners area established more elaborate and lasting lodges that might be circular or rectangular in composition and structure. Over time both the residences and kivas of the later Basketmakers became larger, with inhabitants of each numbering several hundred people and with each village encompassing 100 to 500 rooms and more than a dozen pit houses. Eventually in the late first millennium the Anasazi peoples of the Four Corners regions redefined themselves, as evidenced by the construction of the elaborate Chaco Canyon villages. There the Pueblo Anasazi constructed 11 villages encompassing 100 to 500 rooms each. This so-called Chaco Phenomenon represented a transition to even more elaborate villages and structures. Pueblo Bonito, in Chaco Canyon, grew larger

and larger so that by 500 CE it was one of the most populated villages found in the canyon. Moreover, after 500 CE the Anasazi there began to substitute their pit houses for aboveground houses, which evidences their further development and refinement. These peoples continued to evolve, but by the mid-eleventh century they had reached their zenith.

In terms of the political-social system that developed among the peoples of Chaco Canyon and beyond, much debate among archaeologists has occurred and continues today. Some scholars such as James Judge have postulated that the initial loosely configured farming communities of the Anasazi gradually grew larger (Pueblo Bonito became the primary community in Chaco Canyon), which resulted in a more elevated hierarchy. Field research over generations has unearthed differences in burial sites, which indicate that social stratification was present in Chaco Canyon. Though still debated, this circumstance would suggest that some people held greater social distinction and with it perhaps political power. If true with regard to the latter, this would support the notion of those who contend that what emerged with Chacoan people was a state. One of the more prominent of those supporting the idea of a Chacoan state, David Wilcox, has articulated the view that outlying communities became tributaries to Pueblo Bonito's more prominent families/clans. Yet another archaeologist, Steve Leskon, who researched the Chaco State Theory via the outlying communities with Chaco Canyon and its periphery, found similarities in their architecture, thus suggesting that Pueblo Bonito was not just a ceremonial center but in reality was the capital of the Chaco state. Whether there actually was a Chacoan state will undoubtedly cause the present and future archaeological community to continue to ponder.

Early Mesoamerican States

During the Classic Period, a number of Mesoamerican polities arose that rank as states and empires. These states and empires differed in many significant ways from those established in the rest of the world. However, they exhibited a high degree of sophistication, and their rulers were able to exert a large amount of control over their people.

Mesoamerican states were unique because they existed at a stone-age level of technology. Virtually all tools, weapons, and mechanical devices were created from stones of different kinds and wood. Manufactured goods consisted of workings of these basic materials. Mesoamerican states were also unusual in the world because most of them lacked the type of cities found in Asia and Europe. Relatively compact areas of dense population were rarely found in Mesoamerica during the Classic Period. Only a few examples, such as Monte Alban and Teotihuacan, can be cited. Instead, most states were centered upon small religious and administrative centers. The centers contained temple buildings such as pyramids and the homes of the rulers and their retainers. Some specialized craftspeople also lived in the centers and created products for use by the elites or for trade. Most of the population lived in multigeneration farm homesteads, close to the fields they worked. As a result, it is possible that hundreds of small independent states existed in Mesoamerica.

Politically, Mesoamerican states were more complex than the political entities that had come before. They had a ruling class that had few or no direct family links to common people. Status was inherited, not earned. Kings were able to demand forced labor from their people, to create temples and palaces, and to fight in wars if necessary. Kings were regarded in Mesoamerican states as being descended from the gods. A society's well-being depended upon keeping the gods and their king pleased. To as-

sert their special status, kings, members of the ruling family, and the nobility openly demonstrated their special status through displays of wealth, conspicuous consumption of luxury goods from other regions, or the creation of monumental works. These displays often helped shore up the authority of a ruler who lacked institutionalized power over his people.

The first Mesoamerican states arose when ambitious chiefs conquered nearby polities and asserted their authority over them. Ordinarily, this assertion took the form of demands for labor. This conquest created a new hierarchy of officials who ruled over conquered areas.

One of the first Mesoamerican states was Teotihuacan, in the Basin of Mexico. Teotihuacan grew rapidly, and its rulers resettled most of the population of the basin within its boundaries. This resettlement helped Teotihuacan's rulers to control the different groups who were assimilated into its population. By 150 CE, Teotihuacan had a population estimated at 80,000. The city's size helped to discourage rivals. The earliest projects by Teotihuacan's rulers included two massive pyramids, dedicated to the sun and the moon. Later projects included massive apartment complexes for its people and public works like irrigation canals to support intensive agriculture. Teotihuacan expanded the areas under its control to include corridors of territory into regions that provided trade goods. Teotihuacan became Mesoamerica's first empire, incorporating numbers of peoples who had been previously independent and did not share an ethnic heritage with its founders. Trade was probably one of the driving forces behind the expansion, especially trade in products such as gold, silver, cacao beans, feathers, and other luxury goods for the noble classes. The centralized government at Teotihuacan and its ability to demand forced labor from its people gave it an advantage over its neighbors. Although Teotihuacan left no written materials, archaeologists believe that the surviving artwork indicates that the people of Teotihuacan were regarded as interchangeable units, expected to work for the good of the rulers.

A similar process occurred in the city of Monte Alban, which was founded by people living in the Oaxaca Valley. The city was built on a

defensible mountaintop, with two miles of walls around it. Satellite settlements were established to provide forward defense and to make agriculture easier. Extensive canals were constructed by centrally directed forced labor to increase the production of food. The Zapotec state continued to expand and incorporate surrounding peoples until it covered around 7,722 square miles. The city of Monte Alban began to shrink after 300 CE, with people resettling in the surrounding villages. It remained a religious center, however, and was the destination of pilgrims.

Smaller states were founded among the Maya in the Mexican highlands and lowlands. These city-states were greatly influenced by Teotihuacan and the Zapotec states. These influences came through trade exchanges as well as military conflict. Tikal, for instance, was one of the earliest Mayan states. It used military conquest and shrewd diplomacy to dominate and incorporate its neighbors. The complete elimination of a rival ruling family and its replacement by a member of Tikal's dynasty was one method. Another method was the desecration of religious sites in conquered cities and their replacement by sites dedicated to Tikal's gods. In this way, Tikal managed to combine physical conquest with spiritual conquest. Actual military conquest by Mesoamerican states was relatively rare because the logistics required were beyond their capabilities. Many warriors were only available during part of the year because of agricultural requirements. Also, lack of pack animals and wheeled vehicles ensured that only the supplies carried on human backs were available.

Palenque was another important Mayan city-state. Located on the northwestern edge of the Maya Lowlands, Palenque was located close to a cacao-growing area and blessed with six rivers for easy water transportation. The city was discovered in the seventeenth century and remains one of the best-preserved examples of Mayan architecture and art. The site was occupied until the late eighth century. Most surviving structures and historical records date from 600 to 800 CE. Beginning with the king Pakal during the seventh century, Palenque became an important ceremonial center. The many temples and religious structures help make Palenque's history the best documented in Mesoamerica.

Photograph from the Pyramid of the Sun at Teotihuacan illustrates the elaborate and extensive building characteristic of early Mesoamerican states. (Corel)

Calakmul was a major urban center in the southern Maya Lowlands between 300 and 900 CE. The size of the structures shows that the rulers of Calakmul could organize both people and materials to create large projects. Calakmul's rulers were also able to exert their influence over their neighbors. Palenque's well-documented history indicates that it was conquered by Calakmul shortly before Pakal ascended to the throne. Other Mayan cities were tributaries to Calakmul until the region experienced political fragmentation in the ninth century. The city may have had a population of up to 75,000 people.

Copan was the southernmost Mayan state during the Classic Period. Located in modern Honduras, Copan had a population of around 25,000 and exerted influence over a large area. Its rise to greatness was apparently begun by a ruler from Teotihuacan around 426 CE. A program of constructing temples and ceremonial courtyards helped cement Copan's importance to the region. Surrounding settlements were reduced to tributary status. By the early eighth century, the king of Copan could claim equality with Palenque, Tikal, and Calakmul on his monuments. The city collapsed during the early ninth century as a result of overpopulation and ecological degradation.

Yaxchilan was an important Mayan city overlooking the Usumacinta River. Its many monuments are notable for their depictions of women. They also allowed scholars to decipher many of the ritual images used throughout the Mayan

world during this time. Yaxchilan established many alliances during the Classic Period, including close relations with Calakmul. These shifting alliances may have led to Yaxchilan's collapse around 808 CE. Excavations at the central ceremonial complex revealed many projectile points, indicating that a final battle took place there around that time.

After 800 CE, the existing Mesoamerican states began to decline. Most were apparently the victims of internal divisions. The demands of the ruling families and nobility for labor and luxury goods put ever-increasing pressure on the common people. The gulf between the classes also increased. Villages became more autonomous, and the power of centralized state governments declined. Some cities show signs of having been looted or destroyed by fire between 800 CE and 1000 CE. By 900 CE, the Classic Period had come to an end, with only a collection of petty city-states throughout Mesoamerica.

The Teotihuacan Empire, 300–650 CE

Teotihuacan was the first empire in Mesoamerica during the Classic Age that stretched from 300 to 900 CE. It was one of the largest cities in the world during this time, with a population estimated at up to 200,000 people. Until at least 650, Teotihuacan dominated the Basin of Mexico and the surrounding areas. Archaeological evidence indicates it had a strong central government that exerted strict control over many aspects of the population's lives.

The earlier Olmecs had established a number of ceremonial centers that were independent polities. These centers had relatively small populations. Soon after Teotihuacan was founded during the first century before the Common Era, it began to grow rapidly. The ruins of Teotihuacan show signs of city planning, with a two-mile-long central street known as the Avenue of the Dead. The avenue was more than 150 feet wide and ran from the Pyramid of the Moon to a large compound that probably served as an administrative center and central market. By 300 CE at least half of the people in the Basin of Mexico lived in Teotihuacan. The city covered an area of more than seven square miles, but its population density was less than contemporary European cities. One reason the population grew so rapidly was that Teotihuacan was a religious center for the region. The massive Pyramid of the Sun, for instance, was built over an underground lake considered to be the place where humans emerged into this world.

Although the plain where Teotihuacan was located was relatively well watered and fertile, its population depended more on crafts and specialization than on agriculture. Neighborhoods, or barrios, were organized so that people engaged in the same kind of work lived close to each other. One important industry was the production of obsidian and flint tools and weapons. Other industries included the production of ceramic pottery and small figurines. The degree of centralized planning and control by the government of Teotihuacan is obvious. It was greater than that of any prior Mesoamerican rulers. Each barrio had its own ritual center with three small temples. Apartment complexes were built around the ritual centers, making the barrios virtually self-contained.

The archaeological evidence also indicates that Teotihuacan was intended from the beginning by its founders to serve as a trade center as well as a religious center. It was located on the natural routes between the lowlands along the Gulf of Mexico and the central plateau. It also straddled routes from the American Southwest and the Pacific coast. Because Teotihuacan had few natural resources that were unique to its location, it became an important redistribution center. Teotihuacan rulers encouraged trade and

THE LONG LIFE OF THE ZAPOTEC KINGDOM

The Zapotec kingdom of the Oaxaca Valley had a history dating at least to the establishment of a religious and population center at San Jose Mogote by 900 BCE. Four hundred years later, an urban center was founded at Monte Alban as part of the confederation of different Zapotec peoples. Monte Alban experienced a golden age during the Classic Period, starting around 200 CE. The city's rulers gained control over at least 50 surrounding population centers, forcing them to pay tributes of goods and labor. A defensive wall around the base of the mountain protected the city from attacking warriors. The top of the mountain on which Monte Alban was built had been leveled and made into a plaza that included palaces, temples, and a large ball court. Eventually this central plaza became the exclusive precinct of a class of royal rulers, nobility, and priests who maintained the city's religious life. Commoners seem to have eventually been excluded from the central plaza, leading to a growing tension among the classes. Traders from Monte Alban established a separate barrio at neighboring Teotihuacan, and evidence exists of a thriving trade between the two cities. The relationship seems to have been proper but uneasy, since the cities were rivals. After Teotihuacan collapsed

Monte Alban was the center of Zapotec culture until its fall in 900 CE. (Corel)

during the seventh century, Monte Alban underwent a period of decline. The population decreased as more people moved to smaller settlements in the Oaxaca Valley. The population of the central settlement at Monte Alban dwindled from a high of 25,000 to only several thousand by 900. The temples, however, remained a religious center and were visited regularly by pilgrims.

—Timothy J. Watts

established special neighborhoods for merchants from other regions. While exporting obsidian and flint weapons and tools and decorated ceramic pottery, Teotihuacan imported cotton, cacao beans, and luxury items such as brightly colored feathers from tropical birds. The thriving trade brought great wealth to the city and its noble rulers.

To support its trade, Teotihuacan developed a strong military force. Unlike other cultures in Mesoamerica, Teotihuacan developed a militia that used standardized formations and tactics. Weapons were supplied by the state and consisted of short stabbing spears and atlatls that threw darts with great force and accuracy. Teotihuacan differed from conquering empires in the Middle East and Europe, however, because it did not try to conquer and occupy the neighboring states. Instead, trade colonies were apparently established in selected areas, supported by warriors. Corri-

dors under Teotihuacan control were created to make the movement of trade goods safe and easy. Neighboring states were influenced by diplomacy and alliances with Teotihuacan.

One example of a kingdom that was influenced by Teotihuacan was Tikal. Tikal was a Mayan city-state allied to Teotihuacan. Tikal conquered neighboring Waxaktun in 378 CE, probably with military assistance from Teotihuacan warriors. Architecture, art, and culture in Tikal showed influence from Teotihuacan. The Teotihuacan war god 18-Rabbit Snake, for example, was adopted by the rulers of Tikal. Such an adoption showed they believed that Teotihuacan's gods were stronger than their own native gods and could bring them success. A neighborhood of people from Teotihuacan has been found amid Tikal's ruins.

Teotihuacan began to decline during the seventh century probably because of internal

conflicts. An uprising around 650 CE burned much of the city's ritual core. The population declined, although large numbers of people remained in Teotihuacan until the ninth century. Other factors believed to have contributed to Teotihuacan's decline included ecological collapse from deforestation and a prolonged drought as well as the influx of migratory peoples from the north.

Blood and Sacrifice—Mayan City-States

During the Classical Period of Maya civilization, between 300 and 900 CE, many Mayan city-states of different sizes flourished in present-day Guatemala and southern Mexico. The Mayan kingdoms were united in the pervasive presence of religion in all aspects of private and public life. The people viewed their gods as actively participating in the successes and difficulties of daily life. The state was expected to sustain and honor the gods to ensure their assistance and favor. Animal and human sacrifices were a significant function of the state in appeasing and seeking the continued assistance of the gods.

Blood was considered the highest gift that could be offered to the gods. The Mayan term for blood meant “precious water,” indicating the high value they placed on it. Some animals were suitable sacrifices to the gods. Jaguars, with their power, speed, and ferocity, were believed to be especially sacred. However, human blood was the type of sacrifice that best pleased and strengthened the divine beings. Most Mayans practiced bloodletting on themselves. Maguey thorns were often used to pierce earlobes, ears,

tongues, and genitals. In extreme cases, strings were drawn through holes pierced in various body parts. Sometimes the blood was collected on paper. The paper was then burned to produce smoke that rose to heaven.

All blood sacrifices followed strict rituals and rules. The rituals enforced the gods' authority over individuals' lives. A key part of this system was the idea that kings and other rulers of the city-states were representatives of the gods, if not divine beings themselves. Mayan kings claimed the right to rule through authority given by the gods to their ancestors. They inherited their positions through divine intervention and were expected to participate in many activities to keep the favor of the gods for themselves and their people. Sacrifices were required to ensure that the world remained an orderly place.

Human sacrifice had its roots in Mayan myths about the founding of the world. According to one story, the gods gathered to create the sun and the moon to light the world. To create them, two gods had to sacrifice themselves. In other stories all the gods sacrifice themselves to make the heavens and the earth. To pay this debt to the gods required blood from humans.

Human sacrifices had to be sanctioned by the state and could only be performed by a member of the priesthood according to certain ritual rules. Victims were selected according to specific requirements. For example, to bring regular rainfall from the god Tlaloc, children who had two whorls in their hair were selected. The more tears they shed before being sacrificed, the more rain would fall in the coming year. Midwives chose a mature woman who had to weave and dance in the market before being sacrificed. In all cases, the victim was ritually washed and purified before the sacrifice. They were dressed in beautiful costumes or as a particular god.

Many of the victims chosen for more common sacrifices were slaves. The most pleasing sacrifices to the gods, however, were captives gathered in warfare. The more courageous a captive was, the greater the honor and benefit in sacrificing him to the gods. The sacrifice of a valiant enemy was also a victory over that enemy's gods. Warfare was often viewed primarily as a method of gathering victims for sacrifices to the gods as much as for any political or commercial gain. The

warriors who captured high-ranking opponents were rewarded and decorated. They often received ceremonial meals after the sacrifice of their victims, the warriors and their families were served small roasted portions of the victims.

Methods of sacrifice varied. Most took place in public displays before the assembled people. Usually, victims and the priests who sacrificed them marched in procession to the temples where the sacrifice was performed. They often sang and danced along the way. Many victims went willingly to their doom, believing that their death was a high honor. Decapitation was often used against women. Strangulation, burning, and hurling from great heights were also used. The most common method involved the removal of the victim's heart. He would be placed on a sacrificial stone at the top of a temple pyramid, and a priest would cut through his chest wall with a flint knife. The priest grasped the still-beating heart and ripped it out of the victim's chest. He held the heart up for the people and the gods to see before placing it in a ceremonial vessel. The body was unceremoniously tossed down the pyramid. The skull was usually removed and placed on a rack with others for public display.

For the Maya and other Mesoamerican societies, blood, particularly human blood, was the nourishment for the gods that kept the world in order. Sacrifice pervaded all of their culture and society.

➤ LADY SIX SKY

Lady Six Sky was the daughter of Flint-Sky-God K, king of the Maya city Dos Pilas. When the ruling family of neighboring Naranjo was destroyed, Lady Six Sky was sent by her father to establish a new dynasty in that city. Stela recorded her arrival on August 27, 682 CE, and her performance of rituals as ruler three days later. These rituals played an important part in establishing the legitimacy of Lady Six Sky as a ruler. She apparently spilled her own blood as well as that of sacrificial victims to obtain favor of the gods. Female rulers were very rare in Mayan culture, and Lady Six Sky apparently married a Naranjo noble soon after her arrival to further ensure her place. In 687 her son Smoking Squirrel was born and was acknowledged as rightful heir to the throne. She served as official regent for her son. Under Lady Six Sky, Naranjo began a military campaign against its enemies when Smoking Squirrel was five years old. A series of military victories established Naranjo as an important power. Smoking Squirrel's victory monuments always referred to his mother; his father remains unknown. After Smoking Squirrel's death around 726, Lady Six Sky ruled as queen until her death in 741.

■ Introduction: Andean Political History

Political life rose to new heights and importance during this era that roughly corresponds to what is called the Middle Horizon in Andean archaeology. Among the diverse sociopolitical configurations that charac-

terize this period and region, we see the rise of the first true centralized states in South America and the first true urban centers. States included those centered in the Moche Valley on the northern coast as well as those centered on the later

sites of Wari and Tiwanaku in the southern Andes. Urban centers of this period include not only the political capitals of the emergent state polities but also sites such as Ventilla in the Nazca Valley; Gallindo, Pañamarca, and Pampa Grande on the north coast; and Conchapata, Lukurmata, and Khonko Wankane in the southern highlands. Religious pilgrimage, warfare, and political feasting appear as repeated themes explaining what held these emerging polities together.

At least two strong state-level polities characterized this period in the Andes. In fact, the great urban polities of Wari and Tiwanaku have served to define the archaeological Middle Horizon in Peru. Tiwanaku was probably politically less cohesive than Wari, but both states shared important characteristics. Signs of greater centralization include not only the emergence of truly urban centers but also the establishment of multitiered hierarchies of sites in which the great urban centers of Wari and Tiwanaku attained primacy. From the urban centers, polities extended their social, political, and economic influences, creating the first Andean empires. States used a variety of techniques to incorporate new territory including military conquest and domination as well as appeals to sociopolitical ideals. The result was a patchwork of free territories, economic and political colonialism, and clientage.

Decentralized is a more fitting description for the polities that emerged along the northern and southern coasts of Peru during this era. Decentralized polities were characterized by complementary and/or competing urban centers. While these centers maintained shared cultural traits such as the shared iconographic traditions of the Moche and Nazca homelands, no one center maintained any significant control over other centers for any long period of time. Leadership in these polities may not have been strictly hereditary, but the leaders themselves most likely came from chiefly clans or belonged to a class of ritual specialists rather than representing monarchs in a true sense. For this reason archaeologists often refer to Moche centers, for example, as *señorios*, suggesting leadership by a lord rather than a king.

Religious pilgrimage may have played an important role in the creation of urban centers as

well as in the perpetuation and extension of state control. Some pilgrimage centers may have been quite empty except during periods of pilgrimage and ceremony. A similar scenario was once hypothesized for the great Mayan centers but seems to be a more accurate interpretation in many South American centers. Others may have sustained ongoing traffic of religious adherents or continual cycles of rites and rituals. In either case archaeologists have hypothesized a priestly elite that would have directed pilgrims, reified the social order through public ritual, redistributed elite goods, and collected tribute sent to honor the shrines housed within the center. Control of the pilgrimage experience was one way in which elites maintained social influence and control of urban centers, or at least sectors of them. Funerary remains and iconographic evidence suggest that both males and females took prominent roles in the administration of religious ritual.

Warfare, including practices of headhunting and human sacrifice, was another means for political integration and control for states. Polities throughout the Andes during this time period exhibit a variety of evidence for these practices including visual, physical, and architectural data. Much of the evidence comes from visual representations of warfare, armed combatants, prisoners, and disembodied heads. Judging from the prevalence of some of these images, it seems that interethnic violence was commonplace and played a major role in male sociopolitics. In most cases, however, the physical evidence for violence (e.g., decapitated bodies), though indisputable, is much less abundant than suggested by the visual data and includes a combination of both male and female victims. Similarly large architectural compounds, such as those constructed by Wari people, were certainly defensible and intimidating, but evidence that they functioned predominantly as male military barracks rather than as redistribution centers or administrative centers occupied by both men and women is lacking. The male warrior ethos exhibited in pottery and other media lends more credence to this conclusion than does any corroborating physical data.

Noble largesse and feasting also played an important part of Andean statecraft during this time period. Feasting certainly took place in

both centralized and decentralized polities and may have constituted a part of both sacred and secular practices associated with statecraft. One telling category of evidence for this practice is vessels in the shape of elite males or at least elite male heads. Such portrait vessels constitute parts of highly decorative assemblages of storage and serving vessels. Archaeologists have encountered such assemblages in contexts associated with elite burials, ritual offerings and caches, households, and temple complexes. The diversity of contexts for these assemblages suggests that sharing of food and drink served in both sacred and secular functions as ways for the elites to create and maintain social influence. Emergence of such means of political control may also have signaled a dramatic shift in gender relations as elite males sought to control the means of producing feasts. Monopolizing the capacities of female household and kin-group members would have given males greater access to the food and drink required to sponsor feasts.

Moche

The Moche (or “Mochica”) culture produced one of the first true states in the Andean region. Moche culture incorporated 14 valleys along the northern Peruvian coast from Piura south to Huarmey. Renowned for their work as ceramic craftspeople, the Moche produced a distinctive artistic canon that included portraits of elite men and fine-line drawings of various scenes. The content and distribution of Moche art along with impressive monuments and recently excavated burials of fabulous grandeur and wealth suggest a theocratic basis for Moche statecraft.

The Early Moche (100–300 CE) grew out of the Chavin tradition of northern Peru (called Cupisnique on the coast). These early people resided alongside Gallinazo and Vicus groups in the same region. Each valley housed politically autonomous but culturally related polities, sharing cultural ideas but not governance. After about 300 CE, however, Moche warrior-priests gained greater control over populations. These new rulers, for example, could command enough labor to organize impressive irrigation projects and to sponsor the production of fine art in specialized workshops.

During the Middle Moche period (300–600 CE) the state in the Moche Valley expanded beyond the confines of its homeland. The motivation for the expansion is unclear. Unifying several valleys, this emergent state constructed the most impressive monuments ever built in South America at Cerro Blanco, the capital. The adobe bricks contained in these monuments still bear the marks of the work crews who contributed them as part of state taxation. As the state grew, people increasingly adopted Moche ideals and norms, effectively eliminating earlier cultural expressions. More northern Moche polities may have maintained their relative autonomy, producing their own powerful leaders immortalized in exquisite ceramic portraits. All leaders seemingly participated in similar state rituals to reify their power and control, with the same ritual drama acted out by different leaders in different valleys.

In the period from about 500 to 750 CE known as Late Moche, the coast encountered a series of stresses. These included environmental stresses from drought, earthquake, and El Niño disruptions of the coastal fishery. At the same time the Moche experienced contact from the Wari empire as it expanded northward from the central Andes. It also appears that people felt increasingly isolated from their ritual-bound elites. This combination led to political and social reformulations, signaling the collapse of centralized state power. In turn, the reorganization gave rise to the later Chimú polity.

Archaeologists have long acknowledged the narrative nature of Moche art. It was only in the last few decades, however, that they surmised that scenes portrayed in the fine-line style had

THE LORD OF SIPAN

How do archaeologists know that the people shown in Moche art really existed? They long thought that drawings on pottery represented myths, not real events. Discovery of several intact elite tombs beginning with the Lord of Sipan tomb in 1987 allowed archaeologists to draw parallels between the buried regalia of the elites and the costumes consistently portrayed in artwork. The main person in the Lord of Sipan tomb, for example, had many of the same garments, jewelry, and insignia buried with him as did the neighboring Old Lord of Sipan tomb. These match those shown on the main figure receiving offerings of blood depicted repeatedly in Moche art.

The long-standing hypothesis was that depictions such as the presentation theme (a high-ranking personage receiving a chalice of human blood), reiterated numerous times in part or in whole in Moche fine-line paintings, represented scenes from Moche mythology; none of it ever really happened.

Discovery of the Lord of Sipan tomb and other elite tombs radically changed that basic hypothesis. Included with the central individuals in these tombs were elements of the regalia illustrated on the mythic individuals in the fine-line paintings. This suggested that on some level the Moche art in question represented something far more real than originally thought, perhaps elements of a Moche history.

When more than one individual was found buried with the same regalia, interpretations

Reconstruction of the “Lord of Sipan” tomb. (AP Photo/Hermann J. Knippertz)

changed again. Repeated examples of the same costumes now suggest that Moche elite occupied specific roles and reenacted rituals or scenes from myth, generation after generation.

—Jo Ellen Burkholder

direct correlations to the real-life world of Moche politics. The most potent scenes portray individuals in battle and the stripping of prisoners, their sacrifice, and the collection and offering of their blood by a group of priests and priestesses. Evidence from several sumptuous tombs at the site of Sipan allowed archaeologists to equate scenes from Moche pottery with roles held by actual individuals buried with complete sets of ritual regalia. Rituals most likely took place on the top of large platform mounds in full view of the general populace. State ritual was the basis of leaders’ theocratic powers.

Wari

Wari (Huari) might be considered the largest and greatest of the Andean region’s Middle Hori-

zon (400–1000 CE) polities. In its size and scope it may be second only to the Inca empire itself for which it laid some of the physical and social infrastructure. It is somewhat ironic that this large and powerful state, centered in the Huamanga region of Peru, was for many years lost to the annals of archaeology and its impressive material culture confused with that of its more southerly coeval polity centered at Tiwanaku. Current data suggest, however, that Wari was the first of the two great Andean polities to attain a state level of political organization.

Wari origins are mysterious. Wari material culture is clearly derived from that of the Huarpa culture, whose greatest center was probably Nawimpukio, outside of present-day Ayacucho, Peru. Additional cultural influences probably also included coastal Nazca people. Major Wari sites in the Huamanga region may all have been occupied prior to the Middle Horizon, but most saw major reconstruction and reorganization after 400–500 CE.

The centralization of Wari power after 500 CE was founded on combinations of ritual feasting, mortuary ritual, and militarism. Ceremonialism is denoted by the presence of D-shaped temples within high-walled elite compounds. The rituals that took place in these limited-access spaces most likely included drinking of *chicha* (corn beer) from the enormous highly decorated urns that were later smashed in situ. Drinking rituals involving oversized urns, 19–32 inches (50–80 centimeters) tall and 23–36 inches (60–90 centimeters) wide at the open mouth, also took place in other restricted rooms and not just D-shaped temples. Some place the beginnings of the central Andean tradition of ancestor worship and mortuary cults within the Wari tradition, arguing that elites reified their status through visual reference to the physical presence of a noble ancestry.

Assertions of Wari militarism are closely tied to the establishment of regional administrative centers in provinces distant from Wari's natal territory in Huamanga. Such centers date between 750 and 900 CE and include the sites of Pikillacta, Jargampata, Azangaro, and Honco Pampa. Here Wari presence is noted in the presence of orthogonal cellular architecture. These installations were divided into regular room clusters and sur-

➤ THE ROLE OF D-SHAPED STRUCTURES

D-shaped buildings occur at a number of Wari sites, but what functions did these structures serve? As the name implies, these structures are round except for one flattened side. They vary in size to 8 to 59 feet (6 to 18 meters) in diameter, and many contain stone-capped burial chambers beneath the floors and trapezoidal niches in the walls. Recent work suggests that these were places leaders may have gone to offer ritual sacrifices in order to ensure the fertility of the land. By emphasizing the connection between humans who sacrifice and myths of divine sacrifice, leaders may have promoted themselves as divine rulers.

—Jo Ellen Burkholder

rounded by high walls up to 3.4 feet (1 meter) thick at the base. Roads that predate those of the Inca connected many of these sites with the capital city. Where imperial complexes exist, local settlement patterns were often reconfigured at about the time of the Wari intrusion. The cause for this expansion is unclear.

More recent research in the areas of the Colca and Cotahuasi Valleys of southern Peru as well as ongoing research at the anomalous site of Cerro Baul suggest that Wari elites may also have used political and social coercion as a way to gain control over new territory. Clientage and gift exchange may have swayed local elites to provide the goods and services desired by the empire without the threat of physical force.

Tiwanaku

Tiwanaku is the name given to the state-level polity that arose in the southern Lake Titicaca Basin in present-day Bolivia. Though once dated as early as the second millennium BCE, the state-level polity now appears to have coalesced from several regional polities sometime during the period between 500 and 750 CE. Overlap between the artistic canons of Tiwanaku and Wari, its northern neighbor, led many scholars to conflate the two polities, giving preeminence to Tiwanaku for most of the nineteenth and twentieth centuries. Today the emerging picture of the Tiwanaku state is one of a highly influential polity with deep cultural roots but lacking the duration, expansive abilities, and military might of the Wari state.

The cultural origins for Tiwanaku predate its political coalescence. Iconography and temple

architecture associated with Tiwanaku resemble that of earlier cultures of the altiplano region, particularly the Yayamama Religious Tradition. This includes especially strong ties to the iconography of the Pukara and Chiripa cultures of the Titicaca Basin. The emphasis on images of severed human heads on elite serving vessels also suggests connections to the Nazca culture of the Peruvian coast.

Over the last several decades archaeologists have continued to move the date for the emergence of the Tiwanaku state forward in time. Carlos Ponce, one of the first Bolivians to devote his career to the study of Tiwanaku, placed the start of the Tiwanaku state with the earliest habitation of the type site, around 1500 BCE, and placed the apogee of the Tiwanaku state between 400 and 1000 CE. Improvement of dating techniques, a wealth of new carbon 14 assays, and a better understanding of how to archaeologically define Tiwanaku civilization now leads most researchers to place the coalescence of state society closer to 600 CE and the state's maximum influence before 850.

A number of signs mark Tiwanaku's centralization of power. Most obvious may be population growth in the urban capital at the expense of its main satellites, Lukurmata and Khonko Wankane, and the establishment of a multitiered site hierarchy within the Tiwanaku Valley. Other signs of the rising power of the state include abundant large-scale construction projects in the Tiwanaku site's ceremonial core and massive efforts to construct raised agricultural fields. Pervasiveness of a specific ceramic assemblage—a tall drinking cup (*kero*) and a stout bowl (*tazon*)—appears to signal people's incorporation into Tiwanaku's political system.

Three factors appear to contribute to the centralization of the Tiwanaku polity. The most obvious is a pervasive religious iconography. This iconography is similar in content to that of the Wari state, though it is distinct in execution and preferred media. The most important figures were a supernatural being with rayed projections from its head, winged attendants figures shown in profile, and severed human heads. The meaning of this iconography is unclear, though rituals may have involved at least occasional human sacrifice as indicated by human remains

The city of Tiwanaku, located just south of Lake Titicaca in present-day Bolivia, was the capital of the civilization also called Tiwanaku. (Shutterstock)

scattered on the terraces of a Tiwanaku temple known as the Akapana. Unlike the Nazca, however, people of Tiwanaku do not appear to have collected and preserved severed human heads.

A second factor appears to be a kind of factional competition between emerging elites. Researchers have identified areas of elite residential compounds as places where large feasts likely took place. Postulating something like the kin groups found in the area today, many archaeologists now accept the idea that commensal politics would have been one form of articulation between social or ethnic groups. In the course of these interactions elites would strive to produce increasingly larger feasts that would win followers, secure labor, and impress other elites. The basis of these feasts is thought to have been *chicha*, a fermented grain beverage (usually corn) served in *kero* cups. The host also probably served stews based on llama meat and potatoes.

A final factor in Tiwanaku's coalescence may be its economic position within a greater network of southern Andean trade. The original attraction to a place such as Tiwanaku, isolated on a cold and vast plain, was likely its function as a central place for trans-Andean traders. The flat plain was and is ideal for walking long distances up and down the spine of the Andes and is also a convenient place to cross from the desert coast to the tropical forests and back. Tiwanaku sites in the Titicaca Basin show evidence that this contact continued and even intensified as the state developed. Evidence for long-distance trade includes obsidian, precious metals, and animal products from the tropical forest as well as the likely importation of corn from more temperate areas to fuel the production of chicha. In many cases it appears that altiplano people directly colonized places such as the Moquegua and Cochabamba valleys to further economic strategies.

VIEWING THE TIWANAKU PAST THROUGH DIFFERENT LENSES

Interpretations of Tiwanaku politics have been influenced by modern-day politics as well as by the available evidence. Nationalism helped to push dates for the beginnings of the Tiwanaku state back to the second millennium BCE and beyond. As late as the 1990s Bolivian grade-school textbooks cited dates as distant as 40,000 years ago as the date for the Tiwanaku state, making it by far the oldest civilization in the world. Racist thought placed the downfall of Tiwanaku at the feet of the Aymara, the dominant ethnic group in the region, who were said to have invaded the Lake Titicaca area perhaps 1,200 years ago. Today a new kind of nationalism favors a view of a Tiwanaku state made up of indigenous Aymara people with far-flung colonies. Aymara nationalism is the major modern expression of the resurgence of indigenous consciousness in Bolivia.

Nazca

The Nazca culture of the Peruvian south coast, which thrived from 200 BCE to 700 CE, is noted for its elegant pottery, fine textiles, and mysterious Nazca Lines etched into the desert pavement. The political organization of the Nazca, however, is an object of debate among scholars. Some have viewed Nazca as developing into a secular state-level polity capable of expansion to other areas, while most have argued for Nazca as a confederation of related chiefdoms coordinated from a central location. In either case, ritual was a way in which leaders extended their control over the populace.

Early Nazca culture is derived in part from the Paracas and Ocucaje cultures of the Peruvian south-central coast. Early materials date between 200 BCE and about 400 CE. During this

Spider geoglyph, Nazca culture, Peru. (Shutterstock)

► CRAFTS AND NAZCA POLITICAL ECONOMY

Archaeologists identify several characteristics that mark a state. One is craft specialization. In the case of Nazca this has led to speculation. Nazca pottery and textiles are very distinctive, and the images on the best pieces are very complex. This suggests that specialists produced these items. Other indicators of specialization appear to be lacking. For example, archaeologists have not yet identified specialized workshops or production zones, nor do fancy pottery and textiles appear to function as prestige goods available only to elites. Households appear to produce their own fancy goods or to freely barter what they produce for the productions of others.

—Jo Ellen Burkholder

period the site of Cahuachi, in the Nazca River drainage, rose to prominence as a civic ceremonial center. Cahuachi was probably an empty pilgrimage center, with the urban population at sites such as Ventilla/Site 165 in a neighboring valley. Some amount of authority must have existed to coordinate religious and other activities, such as the construction of the geoglyphs or Nazca Lines and reproduction of complicated religious iconography on pottery and textiles. Burials from this period, however, show little status differentiation, suggesting that authority was shifting or transitory. Iconography from this time period does not portray people we can recognize as elites.

Cahuachi and its associated cult(s) appear to fall apart after about 400 CE. The cause for this collapse has been tied to environmental triggers and a loss of faith in cult efficacy. Desertification and severe flooding may both have played a role in undermining people's faith in a religious system focused on maintaining balance between humans and the natural world. It also remains unclear how far the effects of this collapse reached and whether the collapse of organization in the Nazca drainage coordinated from Cahuachi had a ripple effect on societies up and down the Peruvian coast.

Beginning in the Late Nazca period (500–1000 CE), society was drastically reorganized. Researchers argue that the vacuum created by the collapse of the Cahuachi-coordinated system led to intense competition and the rise of self-aggrandizing chiefs or nobles. In particular, droughts during the sixth and seventh centuries made water a highly contested commodity. Organizing labor to create, maintain, and repair irrigation systems allowed some people the opportunity of self-advancement.

Males more so than females could achieve and pass on elevated status. Males did this through armed combat and the taking of trophy heads (mummified human heads) in addition to perhaps managing their group's water resources. In the Late Nazca period men who achieved status appeared in Nazca art, often carrying a trophy head in one hand and a knife in the other.

A parallel emphasis on female fertility may have offered women access to other forms of status. Artists produced many female figurines beginning in the Late Nazca period. These figures have robust proportions and usually clearly depicted genitalia and tattoos of aquatic animals. Many interpret this as evidence of a female-focused fertility cult that developed in the face of environmental degradation.

Economics and Trade

This essay discusses the fundamental material underpinnings of societies in the two phases of the Era of Expanding Regional Civilizations: late antiquity (300–600) and the early medieval age (600–1000).

In this era, a small number of the earth's population continued to gain their livelihood with hunting and gathering economies. These nomadic foragers dwelt mainly in Australia, the depths of Africa's rain forest, the vast northern forests and arctic wastes of North America, the cold reaches of South America's extreme south, and the inhospitable hearts of all the world's deserts. A larger number, but still a very small percentage of the earth's people, made their livings by supplementing a basically hunting and gathering economy with swidden, or slash-and-burn gardening. These seminomadic villagers dwelt in many of the earth's forested regions that circled the globe in the tropics and temperate zones. A larger fraction, but still a small minority of the earth's population, consisted of nomadic pastoralists, herding animals (cattle, sheep, horses, camels) to pastures in the Eurasian grasslands, the steppe surrounding the Sahara and Arabian deserts, or the Arctic tundra (reindeer). But for the vast majority of the world's population during the Era of Expanding Regional Civilizations, sedentary agriculture was the economic mainstay. In the agricultural zones, the majority of the earth's people lived in villages, even though political power centered in the few cities.

Although the seven centuries of the Era of Expanding Regional Civilizations did, on the whole, witness an expansion, the early three centuries, known as late antiquity, experienced a sharp contraction in population, area of land cropped, and economic health. This was due to the Dark Age Cold Period, a 600-year epoch of global cooling (ca. 100–600 CE). During much of this time, while the economies of most of the Afro-Eurasian ecumene were contracting, that of India, which may have benefited by increased rainfall, was expanding. In this phase, India was the most prosperous region and the commercial center of the ecumene.

After 600, another gradual shift in global climates began, which by 800 produced a much warmer climate, and a new epoch began: the Medieval Warm Period, which lasted until circa 1300. During this salubrious phase, China became the economic powerhouse of the ecumene, and most of Afro-Eurasia experienced a level of prosperity that had hitherto been unknown. It was also during this phase that farmers colonized the northern forests of western Europe and Russia, using new and heavier plows that may have been first developed in China.

In Africa south of the Sahara, most of the Era of Expanding Regional Civilizations experienced a gradual but cumulatively impressive economic growth. The cooling of the Dark Age Cold Period does not seem

to have affected this region significantly. The introduction of Asian crops, such as rice, taro, sugarcane, and especially bananas, together with chickens, led to a major population increase by 1000 CE. The development or intensification of trans-Saharan and Indian Ocean trade stimulated increased urbanization in the western Sudan and the Swahili coast during this era.

The Americas, like Africa south of the Sahara, also witnessed growing populations and economies. The Hopewell Mound Builder people in the North American Midwest had declined after 400 CE in the Dark Age Cold Period but revived as the Mississippian Culture with the Medieval Warm Period after 800. The Mississippian culture adopted quick-maturing varieties of Mesoamerican crops, especially maize and squash, and constructed large settlements such as Cahokia, which has been called the largest Native American city north of Teotihuacan. The Pueblo people of the North American Southwest responded in a similar fashion to the moist early centuries of the Medieval Warm Period.

This was the classic era in both Mesoamerica and the Andean region. The Maya cities, Teotihuacan as well as the empires of Wari and Tiwanaku, and the Moche civilization flourished during this era.

Until the modern Industrial Age, agriculture was the economic foundation of all sedentary states. The prosperity and military strength of all great empires was rooted in the fertility and productivity of their soils.

During the early medieval age, all empires depended on the agricultural surpluses of a few “islands” of extraordinary fertility. Thus, the Gupta empire derived its power from the rich black soils of the Ganges Valley; the Tang dynasty’s economic health was based on the fertile, friable, and easily eroded yellow loess of the northern China plain; the economy of the Sassanian empire and, later, the Abbasid caliphate centered on the opulence of the irrigated area

of Mesopotamia called the Sawad; and the Nile Valley with its annual nutrient-laden floods contributed to the prosperity of the eastern Roman empire and later to the Umayyad and Abbasid caliphates. Likewise, the Tiwanaku empire derived its sustenance from the abundant potato yields of its unique system of raised fields in the Lake Titicaca Basin.

Soils in these “islands of fertility” were rich enough that they could be cropped year after year without the necessity of leaving great portions of the arable fields fallow or of rotating crops. In some favored “islands,” such as the Ganges Valley or the volcanic soils of Java or highland Guatemala, it was possible to harvest two or three crops annually without the use of fertilizer.

Usually, agricultural prosperity and, consequently, imperial power depended not only on regions of extraordinary fertility but also on the ease with which this fertility could be exploited, given the prevailing simple agricultural technology. For example, the peoples of the Hopewell and Mississippian cultures could, without plows or draft animals, grow and harvest bountiful crops of pumpkins, sunflowers, and

The prosperity and military strength of all great empires was rooted in the fertility and productivity of their soils. During the early medieval age, all empires depended on the agricultural surpluses of a few “islands” of extraordinary fertility.

maize on the easily worked floodplain soil of the rivers of midwestern North America.

But many peoples practiced irrigation and hydraulic management to optimize production. The Sassanian empire and later the Muslim caliphates paid keen attention to improving the irrigation of the Sawad. (The Sawad has been compared to the Central Valley of California for agricultural productivity.) The Tang dynasty, like most other Chinese dynasties, saw flood control of the Yellow and Yangzi rivers as among its chief duties. In India and much of Southeast Asia, where monsoon seasons were followed by rainless months, local officials as well as kings built large tanks and lakes to catch and store water. The countries in East, Southeast, and South Asia that practiced wet-rice farming were extensive practitioners of water management. Irrigation and hydraulic engineering were not confined to the Afro-Eurasian ecumene. The Pueblo cultures of the North American Southwest, many groups in Mesoamerica (including the Maya), as well as most of the Andean cultures were avid irrigators and hydraulic engineers.

The establishment of the caliphate created a zone of interaction in which the Muslims adopted and diffused crops and agricultural technologies from every civilization in the Afro-Eurasian ecumene. The Muslims adopted crops from India, such as sugarcane, cotton, and rice; from China, such as oranges, lemons, and other citrus fruit; and from central Asia, such as spinach, alfalfa, and eggplant. They grew these throughout Dar al Islam, from Spain and Morocco to the Ferghana Valley and the Swahili coast. Muslim farmers established advanced irrigation systems and began the practice of maintaining soil fertility by rotating crops. By growing many diversified crops, they were often able to have several annual harvests. New agricultural technology, such as wind and water mills for pumping irrigation water and grinding grain and collars for horses and camels for pulling plows and other loads, made the application of energy to agricultural tasks more efficient. Many of these innovations in agricultural technology originated in China but diffused through the Islamic world after the eighth century. Although the European Christians subsequently adopted these innovations, this did not take place until after 1000 CE.

From the eighth to the thirteenth centuries, agricultural production increased globally. Small cities became more numerous, and a few large capital cities appeared. To supply these urban centers with food and cotton, large commercial farms and even some plantations emerged, especially in the Muslim world and China. Of special note were the sugar plantations in southern Iraq and Spain as well as the area of Morocco ruled by the Bhargawata, a schismatic Muslim sect. In southern Iraq, gangs of slaves imported from East Africa worked large sugar plantations, and slaves were common on most plantations and commercial farms as well as on many smaller farms throughout the world.

However, the vast majority of farm dwellers were not slaves, though for most freedom was restricted. Most of the farm population in Afro-Eurasia, the Americas, and Polynesia were peasants who paid tribute in the form of rent or taxes to higher-status landholders. The status of these peasants ranged from slavelike serfs, as in western Europe, to relatively

free tenants in much of the Muslim world or China. In Mesoamerica as in the Andes, the common people also paid the bulk of their crops to privileged elites. Nearly everywhere, sedentary village agriculture produced societies sharply divided between powerful elites who used their control of the means of violence to extract tribute from the wealth-producing peasantry. Often, the privileged elite was a warrior caste. In western Europe and some other regions, the dominance of a servile peasantry by a military elite produced feudalism. In China, Europe, and other areas, rulers “gave” villages and peasants as property to monasteries and other religious organizations. In many lands, the rapacity of the elites, religious as well as lay, reduced the peasantry to a bare subsistence. Only in good years, when there was enough but not too much rain, when crops were not devoured by insects, and when villages were not devastated by marauding bandits or pillaging armies, would the peasants experience a modicum of prosperity. In less fortunate years, famine or pestilence scourged the peasant villages but spared the privileged elites.

Since most peasant villages had little surplus to trade, they attempted to be as self-sufficient as possible, producing most of what they consumed and consuming almost all of their production. Villages and manorial estates functioned as nearly self-sufficient economic units. In slack agricultural seasons, villagers engaged in handicraft, producing agricultural tools, pottery, and cloth of home-produced materials. For most of Eurasia, wool and hemp were important textile materials. People of the Andes, Mesoamerica, India, Africa, the Muslim world, and (after the middle of the era) China used cotton as well. In China many villagers produced silk cloth, while in Africa raffia was frequently used. In Africa and Eurasia, village smiths turned out knives, sickles, and metal tips for plows, but most farm tools were made of wood.

The increasing number of cities, most of which were small by modern standards, that grew up after the seventh century in China and the

eight century in the Muslim world promoted a different economic regime. They were often started as military strong points or administrative and/or ecclesiastical centers, and the economic impact on their hinterlands was important. Because the elites spent in these towns much of the tribute skimmed off the peasant villagers, specialized manufacturing groups to satisfy their

wants developed. Armorers and weapons makers, metallurgists, weavers of common and luxury cloth, makers of fine ceramics and glass, jewelers, and health professionals all swelled the economic demands of the cities.

These cities as well as the rural villages exerted a demand for resources not usually locally available. The most universally needed items—salt and iron—were available in most regions, but because their extraction and processing required special care or concentration of resources, they were easy to tax. Salt was mined from rock deposits, as in Austria, or mines in the Sahara Desert or was extracted from brine wells in Sichuan or collected from evaporation ponds along many coasts, but because everyone needed it, it was usually taxed. Likewise,

The increasing number of cities, most of which were small by modern standards, that grew up after the seventh century in China and the eighth century in the Muslim world promoted a different economic regime.

iron was used throughout Eurasia and Africa, but the logistic of iron smelting required large investments in capital and labor. Like salt, iron was frequently subject to a tax. This was true especially in China, the largest iron-consuming and iron-producing region.

The capital cities of the great empires and major kingdoms were in a special economic category. The principal function of these imperial capitals was the care and feeding of the imperial family; the officials who administered the empire; the clergy, including, in Christian and Buddhist states, the great monasteries that were the spiritual guides; and the large capital armies. This care and feeding required hundreds of thousands of servants and slaves, artisans and tradesmen, construction workers and transportation workers, and carters and water carriers and numerous specialists to care for the medical needs of the large populations of these cities. These capitals rivaled in population the huge populations of Rome when it commanded its classical empire. Often the population of a great Early Medieval capital exceeded the combined populations of all other cities, towns, and other urban centers within its empire. Often, great capitals such as Constantinople, Baghdad, and Chang'an were multiethnic and polyglot (though this was less true of the Korean capital, Kyongju, or the Japanese capital, Heien). Another reason for the special nature of great capitals is that their populations were divorced from the land and the peasant villages to an extent that could not be even imagined by the denizens of any other city in the empire. Everything the capitals' residents consumed, whether food, clothing, or often even water, had to be purchased daily and brought in from distant regions. Unlike the case with most of the smaller cities, the huge populations of the capital cities exerted demands for food as well as other necessities and wants that could not be satisfied by the produce of their immediate hinterlands. Often, necessities such as grain, salt, wool, cotton, and animals for slaughter were transported or driven in from provinces not immediately adjacent to the great capital. Smelted iron for tools and weapons, horses for cavalry mounts, timber and sometimes stone for the construction of dwellings and monuments, materials for construction of naval and merchant vessels, and replacements also had to be imported from distant provinces or from across the frontiers.

During the centuries of late antiquity, 300–600 (also known as the Age of Southernization), India's economy was thriving, and India was the focus for trade with central Asia, China, Southeast Asia, and the Mediterranean world. During this period, India exported cotton textiles, precious stones, iron weapons, and religious items and imported wool, horses, and rare woods as well as gold and silver. In these centuries, the Sassanian kings of Persia attempted to monopolize trade between India and the West, but the Romans partially outflanked the Persians by buying from the Arabs and Ethiopians, who became middlemen in trans-Indian Ocean trade. This was the heyday of Ethiopia as an important factor in Indian Ocean trade.

These centuries also saw the beginning of the use of camels in the trade route across the Sahara. In the Americas, these centuries were the golden age of Teotihuacan as a great Mesoamerican metropolis and trading center.

After 400 CE, the economic vitality of both the Mediterranean world and China became much impaired, and by 500, that of India began to wither. Trade across the Eastern Hemisphere declined significantly, though it did not stop.

Then, beginning in the seventh century, Eastern Hemispheric trade across the Indian Ocean, the Eurasian steppe, and the Sahara Desert experienced a spectacular advance. The nearly simultaneous emergence of China's Tang dynasty and the Muslim caliphate had two important results that promoted trade. First, both of these great empires established law and order over large areas by suppressing brigandage and protecting property. Increased security resulted in heightened economic activity.

Second and equally important was the demand created by the establishment of the large and opulent capital cities, Baghdad and Chang'an. Wealth poured into these capitals, and the wealthy classes of each demanded the luxuries produced by the other. The Silk Roads across the desert and steppe from Chang'an to Baghdad and beyond revived, as did the oceanic route from Baghdad to the southern coast of India, then across the Bay of Bengal to the Sumatran port of Srivijaya. In Srivijaya, Arab, Persian, and Indian merchants met traders from China. Srivijaya became an important oceanic trading city. Likewise, Dunhuang, Samarkhand, and other central Asian caravanserais became important in the overland Silk Roads. Along these maritime and overland transhemispheric routes, silk, fine ceramics, lacquer, paper, and, toward the end of this era, tea flowed west, while to China went horses, furs, hides, amber, wool, silver, and gold.

Much of this gold originated in West Africa, where it was obtained by Berber traders who sent it, along with kola nuts and slaves, by camel caravans across the Sahara Desert to the Mediterranean coast, to enter the stream of trade ending in China. For West African gold, the Berber traders exchanged salt from the Sahara Desert as well as horses and metal weapons from the Mediterranean countries.

The Swahili cities on the African East Coast were also actively involved in the transhemispheric trading system. Swahili merchants

Swahili merchants traded with Arab, Persian, Indian, and occasionally even Indonesian or perhaps Chinese traders and exchanged elephant ivory, rhinoceros horn, rare woods, and pig iron for Chinese ceramics, Indian manufactures, and other products.

traded with Arab, Persian, Indian, and occasionally even Indonesian or perhaps Chinese traders and exchanged elephant ivory, rhinoceros horn, rare woods, and pig iron for Chinese ceramics, Indian manufactures, and other products.

Europe was at this time peripheral to the main stream of world commerce, but even there the upsurge in transhemispheric trade found an echo. Increased demand by the Muslim world for European raw materials and slaves resulted in the

growth of a timber trade on the north coast of the Mediterranean and a steady market for Slavic and Irish slaves captured in Viking raids and in the wars between the Christian West Europeans and the pagan Slavs.

In the Americas, the increased economic activity resulting from the wet centuries, which preceded the Medieval Warm Period, stimu-

lated broader trading systems. Important networks developed in the Mississippi-Missouri-Ohio Basin, in Mesoamerica, in the Andes, and probably also in the Amazon Basin as well as in the Caribbean. Dugout canoes along the rivers and seacoast transported trade items, but overland trade depended on human bearers, supplemented in the Andes by llamas.

The Hopewell people of the Mississippi-Missouri-Ohio Basin traded extensively along this river system, importing obsidian from the Yellowstone area, copper from upper Michigan, and seashells from the Gulf of Mexico. The great Mexican metropolis of Teotihuacan, as mentioned previously, traded extensively, sending obsidian tools and artwork to the Mayan cities of Central America and to the Hohokam of the Salt and Gila rivers in present-day southern Arizona. In South America, trans-Andean trade also focused on obsidian but also dealt in *Spondylus* shells from the Ecuadorian coast and, after 600 CE, in bronze from the Tiwanaku area.

Trading systems used a variety of materials as currency during the Era of Expanding Regional Civilizations. In Africa south of the Sahara, cowry shells from the Indian Ocean as well as gold dust and small curved copper ingots served as media of exchange. In the Andes, *spondylus* shells from the Ecuadorian coast were used. In China, in the first centuries of this era, bolts of silk were used as currency, especially in China's foreign trade, but for domestic trade, copper cash (*banliang*), which could be strung together due to the square holes in the center of each, were more commonly used. In the ninth and tenth centuries, after the development of woodblock printing, leather and paper notes, often printed by private money changers, were sometimes used, but it was not until the Song dynasty that the government began issuing paper money. The Muslim caliphates issued the most widely used money outside of China. The earliest Muslim coin, the gold dinar, began its life as a Muslim copy of the Byzantine gold solidus, or *hyperpyron*, and this continued to be used, especially for trade with India. But the most currency from the Atlantic to China was the Abbasid silver dirham. Compared to gold, silver was relatively abundant. The Abbasids developed very productive silver mines in central Asia. Silver from these mines was minted into dirhams, hoards of which have been discovered from England to Russia and from the Carolingian empire to China. The silver dirham was the common currency for much of the Afro-Eurasian ecumene.

—Wilfred J. Bisson

■ Introduction: Agriculture in Early Medieval Economies

In the period from 300 to 1000 CE, more than 90 percent of people the world over engaged directly in agriculture and animal herding, and these pursuits produced most of the wealth, known as the gross domestic product (GDP), in nearly all societies. Agriculture produced food,

silk, cotton, wool, and other textiles. The farm and pastoral population supplied horses and men for the world's armies and produced food for the warriors and fodder for the horses. Nearly all early medieval states obtained the greater part of their revenue by taxing agriculture. Many

states, especially in China, India, and the Muslim world, invested heavily in public works, such as the construction of flood-control and water-impoundment dams, irrigation canals, and the like, with the aim of increasing the economic yield of agriculture.

The country people (peasants) who worked the land were sometimes free but more often existed in some degree of unfreedom or dependence. Sometimes they were chattel slaves, as were those who labored on the sugar plantations in the south of Iraq or on occasional great farms operated by rulers or monasteries. More often, the peasants were serfs who had their own plots of land but paid dues in labor and produce to a lord. Perhaps equally often, especially in Muslim countries, peasants were tenants who paid for the right to a plot of land by paying the landlord a share of the produce as rent. And much less frequently, peasants were free farmers who owned their land and paid taxes on it directly to the state. But free peasants often slipped into debt peonage and eventually types of serfdom by falling into debt because of crop failures or other disasters.

Some governments, reasoning that the health of the kingdom rested on the welfare of the peasants, took measures, such as the Byzantine Farmers Law or the equal field system attempted by several Chinese dynasties, to prevent peasants from losing their land and freedom. These measures never long survived the economic and social pressures of the times. It was more common for states to take measures to prevent peasants from fleeing their lands to free themselves of the onerous burdens imposed on them by landlords and governments.

Monasteries were importantly engaged in agricultural economics in this age. In Buddhist countries, rulers often gave gifts of land and peasants to monastic institutions. The peasants became serfs, but the monasteries grew wealthy. In Europe this practice involved Christian monasteries, which sometimes used the wealth to expand the area under cultivation.

From the eighth through the eleventh centuries CE, the introduction of new crops, which culminated in an Islamic agricultural revolution, stimulated the emergence of a group of agricultural entrepreneurs who made, for a few cen-

turies, agriculture in the Muslim world very productive, nearly approaching the productivity of Chinese agriculture. Investing in irrigation systems, slave-manned sugar plantations in southern Iraq, and market gardens in the vicinity of the cities, Muslim agricultural entrepreneurs made the Islamic world the most productive civilization in western Eurasia.

Agricultural Innovations in East, Central, and Southern Africa

Between 300 and 1000 CE, Bantu-speaking peoples moved into the diverse ecological areas of East, central, and southern Africa. They adapted agricultural technologies from the people already living in the region and invented new ones. They were able to settle and create food-producing niches by raising cattle in the drier regions where there were no tsetse flies and agriculture in the areas of better rainfall where tsetse flies could breed. The gatherers and hunters continued their form of food production and offered alternative sources of food in areas where agriculture or livestock raising was more precarious.

By 500 CE the gathering and hunting peoples in southern Africa had added livestock raising to their food-producing strategies. Bantu-speaking cattle herders supplemented their food production by learning the techniques for the gathering of plants, small animals, and insects of the area and how best to hunt the larger animals that roamed southern Africa. The integration of these various technologies for food production was probably the result of trade between the gathering and hunting peoples who could trade

animal hides and ostrich eggshells for Bantu-manufactured goods such as iron pots and tools, baskets, and woodcarvings. By relying on more than one food-producing technology, these peoples ensured survival in times of crises.

The click sounds, a trademark of Khoisan languages, are found in all the Bantu languages of southern Africa today. Bantu adoption of the click is linguistic evidence of the continued close contact over a long historical period among the gathering and hunting peoples and the Bantu-speaking peoples of southern Africa.

The successful cattle keeping/gathering and hunting strategies also transformed the agricultural peoples of southern Africa. As soon as they began raising cattle, farmers moved into the drier savanna areas, expanding the Bantu-speaking populations and settling new lands.

In east-central Africa by 300 CE, food-producing communities had settled for the first time. The earliest of such communities were Bantu-speaking peoples coming from East Africa, bringing cattle into the drier open savanna areas of east-central, central, and southern Zambia. Their expansion caused the eventual assimilation of the former Khoisan-speaking people of those areas into their societies. In land with good rainfall they grew grain crops. The Batwa fishing, gathering, and hunting peoples persisted as culturally distinct in the swamps and wetlands around Lake Bangweulu.

Beginning around 600 CE, another group of Bantu-speaking peoples, the Sabi, moved from the Congo south into east-central Africa, where they adopted the agricultural techniques of the earlier peoples. They also added a technological innovation of their own in the form of slash and burn agriculture known as *citemene*. The land was not very fertile, so people began burning the trees on the savannas to prepare the soil for agricultural production. The ash from these burned trees provided the soil with essential nutrients. Increasing fertility allowed the Sabi to populate a region of marginal fertility. In the drier sections of southern Zambia the Botatwe absorbed the former cattle-herding peoples and began raising livestock themselves. They also continued with their own type of *citemene* agriculture in the wetter, possibly tsetse fly-infested areas.

In the rain forests of the Congo Basin of central Africa, Bantu-speaking peoples had cultivated yams since 3000 BCE, but around 600 CE bananas, an Indonesian crop, were introduced. Banana crops produced ten times more food than yams and were even better suited for the evergreen rain forests of central Africa. Also, banana cultivation was less labor-intensive, which led to higher population densities among the Bantu-speaking farmers. In central Africa there are more than 120 different varieties of bananas compared to only 12 types in Asia. Banana production allowed the agriculturalists to move into areas that had not been suitable for yam cultivation.

During the seventh century CE around Mount Kenya in East Africa the Thagiicu were still growing African yams in the damper higher regions but were also growing bananas, Southeast Asian yams, arrowroot, and later taro and sugarcane. In the drier lower lands the Chagga grew sorghum and pearl millet. These differing crops in a relatively small area allowed the development of intricate trading networks, which would eventually result in small states.

By 700 CE in the Western Rift to Lake Nyanza, the population of Lake Bantu peoples had grown considerably. The need to place more land into agricultural production of bananas led to deforestation. Areas that were once thick forests by 1000 CE were becoming open grassland savannas. While deforestation seems like a disaster, the net effect of deforestation for the Lake Bantus was that it made the land excellent for livestock raising by removing the habitat of the tsetse fly. Soon communities, like the Batutsi, began to depend primarily on cattle raising and were able to expand and later play a major role in the development of the region. These cattle herders in turn helped the farmers. Fallow land could be used for grazing cattle, while the droppings of the cattle would help to fertilize the land and decrease the fallow time. The success of blending of the agricultural and livestock technologies resulted in larger population growth.

Bantu-speaking peoples had migrated in various ecological zones in East, central, and southern Africa. They adapted food-producing techniques from the peoples they encountered and innovated new methods. Their agricultural success laid the basis for several centralized

states in the future but also allowed people in less fertile areas to continue to live in and maintain their own decentralized communities. Gathering and hunting peoples, in some cases, were integrated into the agricultural societies, but many maintained their independence in part due to their ability to produce ivory and other items for the developing Indian Ocean trade.

Early Java Rice Culture

In early Java, as elsewhere in early Southeast Asia, there was an important dichotomy between swidden (“garden,” “slash-and-burn,” or “shifting”) “dry” cultivation and *sawah*, or “wet-rice” agriculture. In the earliest periods swidden cultivation was practiced in both upland and lowland locations. Annual cereal grass grains that could be grown in relatively dry or wet conditions were supplemented with tubers and yams (*ubi*) gathered from nearby forests or grown in local rain-fed garden fields. The people of Java also cultivated a variety of vegetables and sago palms, another source of starch, as well as fruit, sugarcane, and coconut palms (some for eating and others for their oil), all of which was available at regular three-month intervals because of the short growing seasons these products required. In addition, they raised pigs and fowl. Though this method of production produced a stable food supply, it was not a useful basis for the establishment of urbanization and states, as the fields, rivers, and lake productive centers of the lowland swidden farmers tended not to produce large food surpluses. In addition,

lowland swidden cultivators had scattered low-density settlement patterns similar to those of the highlanders of later periods, and because their settlements tended to be some distance apart rather than contiguous, their aggregate revenue potential was limited, and it was relatively difficult to extract surpluses for export or state development.

In addition to the gardens of the lowlands, dry grains were associated with the shifting cultivation of the highland areas. Modern studies of upland swidden cultivation have shown that it requires less labor per unit of production than does lowland wet agriculture. In the highlands a new patch of forest is cleared and burned each year in preparation for a new crop. The planting process normally uses pointed sticks to make holes in prepared mounds into which two or three grains are placed and then covered over with more soil. The newly cleared fields are initially highly productive due to the nutrients added to the soil in the initial burn-off. However, these nutrients are washed away by rain within two seasons, thus necessitating constant movement to new fields. These migration cycles, together with the relatively low yield per acre/hectare, limit swidden population density to 20 to 30 persons per square kilometer. The low productivity compared to sawah makes it difficult to collect surplus for urban development or for export. In addition, the producing populations are less tied to place than are their wet-rice-producing neighbors. Lowland dry grain farmers would presumably have shown similar distribution patterns, thus impeding the early formation of states. All of this would change with the spread of wet-rice (*sawah*) cultivation.

As sawah agriculture spread in the first millennium CE, swidden production was displaced from much of the lowlands, for the two types of cultivation are incompatible. In the pre-1500 period, garden cultivation never entirely disappeared from the less densely settled parts of the lowlands, as Java’s rich volcanic soil sustained ongoing cultivation although with consequent local population limitations. It is generally believed that sawah cultivation was already becoming common in Java during the early Christian era, though surviving records definitively substantiate only that wet-rice agriculture

was being practiced in eastern Java by the eighth century, coincident to the rise of the first continuous states.

The transition from shifting dry cultivation to settled wet-rice agriculture may have been induced by population pressure as some have suggested, but it was more likely due to a supportive physical environment, a combination of readily available fertile soil in riverine plains that were conducive to early irrigation agriculture and the consistency of seasonal monsoon rainfall. The physical environment was thus a facilitating factor rather than a causative one, which paired with (or contributed to) supportive sociocultural-psychological factors. Wet-rice agriculture could have been considered more convenient, as farmers did not have to move all the time or range as far to gather the means of subsistence. Wet-rice cultivation put farmers in a different kind of trade network, which in turn suggests lifestyle/culture changes of additional kinds. Security, status, and emotional well-being were additional motivations for preferring sawah, and the transition to sawah was accompanied by a fundamental reversal of people's relationships to the forest, which was now perceived increasingly as a zone of wildness and danger rather than a source of livelihood. All of this indicates that whether encouraged from above or adopted from below, the adoption of wet-rice agriculture was intertwined with larger cultural shifts.

Java's sawah cultivators practiced the labor-intensive cultivation method of transplanting rice seedlings, a wet-rice production method that depended on irrigation and was more labor-intensive than the broadcast or banded and plowed floodplain techniques used by wet-rice farmers in Cambodia, Thailand, and Myanmar (Burma). In the transplanting method used in Java, seed was annually sown in small seedling beds at the approach of the rainy season. While seedlings took root, farmers and families prepared nearby fields; they weeded and broke up soil with wooden, stone, or metal-tipped hoes until the monsoon rains soaked the earth. Then seedlings were transplanted by hand, with enough space between for each plant to grow. As the crops matured, farmers repaired the local irrigation system and regulated the flow of water

➤ WET-RICE CULTIVATION PRODUCTIVITY

Transition to wet-rice cultivation is widely believed to increase the productivity per unit of land. But does it produce a similar benefit for the individual farmer? It used to be a common belief that the move from swidden, or dry cultivation, to wet-rice cultivation gave the individual cultivator a greater yield per unit of labor and that it was this increased welfare and prosperity that made possible the formation of early Indic states in Southeast Asia. However, this was not necessarily the case, as we now know that wet-rice cultivation did not necessarily produce more per unit of labor. Recent studies have collectively shown that today's upland swidden cultivators have no less than an 88 percent higher return on their labor than those lowlanders who practice irrigated agriculture. Earlier, when swidden cultivators would have sown in primary growth forest, their yield could have been as much as 124 percent higher than wet-rice farmers, more than twice as much product for the effort invested. Why, then, would a rational peasant farmer commit to wet-rice agriculture? Clues are offered by interviews with today's peasant farmers, who commonly stress the desire for security and personal and familial well-being—physical and psychological—as the two most important motivations in their lives. Wet-rice farming addresses those concerns.

—Kenneth R. Hall

as rains reached their peak. As water receded, fields were drained, and the sun ripened the grain. At harvest, the entire community worked side by side. Javanese women harvested using a finger-knife that cut only one stalk at a time rather than using a sickle, which might offend the local rice spirit and thus jeopardize future production. During the subsequent dry season, fields were cleared, tools were repaired, and feasts, festivals, and marriages were celebrated.

Wet-rice production might be affected by periodic disease and plagues, including the mice plagues that are depicted in ninth-century temple bas-relief. Nevertheless, the food source was relatively stable. Furthermore, there was no need to move to new fields because soil nutrients were replenished via the combination of water flow, plowing under of harvested crops,

algae growth on stagnant water, and also duck droppings. In early times one rice crop normally proved adequate to supply local needs, although a second crop could be harvested if weather and irrigation facilities permitted and if there was incentive to produce a surplus for external sale and consumption. Double-cropping was not necessary for Javanese farmers' subsistence. Nevertheless, by the early fifteenth century double-cropping of rice would be common, as by this time Java's rice had become a valuable exchange commodity on the international trade routes.

Even without double-cropping, sawah agriculture could support an elevated population density due to its ability to generate high yields from small areas. In contrast to swidden cultivation, which supported only 20 or 30 people per square kilometer, with sawah cultivation a field of 2.5 acres (1 hectare) could well support a household of up to 10 adults and children. Also in contrast with swidden, which favored constant population movement, under sawah farmers tended to be tied to particular places, as the rights to occupy and use land were characterized by long-term commitment to a soil plot. Sawah cultivators could occupy the same lands for generations, and because they had little need to move, they were ideal producers of surplus. Nevertheless, in the early sawah regions, large population centers were the exception. It was more common for people to congregate in small housing clusters (one house and one field or several houses and nearby fields), as these were more practical for flooding and draining the fields. Too much water flow would damage the dikes, while too little would result in unwanted algae growth.

Initially at least, irrigation systems were rarely built and controlled by a political authority, though inscriptional evidence suggests that the early states began playing a more direct, albeit still limited, role after the royal center had moved to eastern Java in the late tenth century. Control of water would have been important in dry areas, notably in two "dry zones," one in the coastal mountainous region of western Java and the other in the similarly mountainous region at the eastern end of Java, where annual monsoon rainfall was unpredictable. But rainfall was plentiful elsewhere, and where there were many rivers useful for irrigation, elites would have had to

employ excessive numbers of functionaries to build, maintain, and control a water system, and in the early polities of central and western Java this was apparently a disincentive to direct royal involvement.

Agriculture and Rural Life in Japan

Agriculture and rural life in Japan between 300 and 1000 CE encompassed two separate phases. Between 300 until about 730 the archipelago's population expanded from approximately 1–3 million to more than 6 million. Between 730 and 1000 the population stopped growing, as did the amount of cultivated land. This stasis was caused by high mortality due to epidemics imported from the Asian continent, famines induced by an unusually dry and hot climate, and erosion and other ecological damage created by the untrammeled harvesting of lumber in the Kyoto-Osaka-Nara region.

The evidence for this first phase comes almost exclusively from archaeology, as reliable written records did not exist until about 700. Still, it is likely that the population grew and helped fuel an expansion of cultivated land, especially paddy rice. Evidence for land-clearance activity comes from scattered written comments, archaeological data on the disturbance of forests, and ancient rice paddies uncovered all over Japan.

Early farmers conducted rice cultivation according to the lay of the land and the height of the water table. In many areas, such as that represented by the famous Toro site in Shizuoka pre-

fecture, peasants merely scattered grain upon the low-lying swampy land and then harvested in the fall with stone reaping knives, clipping off each sheaf individually. Similar techniques were applied at higher elevations where enough rain fell to permit natural irrigation. Tools such as hoes and spades were mostly wooden. Draft animals were not employed.

By at least the eighth century a second and more sophisticated mode of paddy cultivation had developed. Farmers prepared seedbeds, sprinkling them with rice seeds, and then transplanted the seedlings to flooded paddies. In this system, men and women harvested the rice at the stalk with an iron sickle, and iron-tipped hoes and spades were more common. This newer system yielded greater harvests but also required a greater input of labor, which became scarcer as the population curve flattened and then dipped after 730.

Scholars are relatively well informed about rice cultivation compared to other crops because polished white rice was the preferred grain of the ruling elite and also served as a unit of account. One record indicates that by around 950 there were about 2.586 million acres of paddy land in Japan, cultivated by a population of about 4.5–5.5 million. By 950 the agricultural cycle was highly ritualized, including ceremonies intended to please the gods of the soil; chase off birds, insects, and disease; and pay homage to the ancestors. One crucial aspect of this agrarian cycle was the breaking up of soils uncultivated in the previous year. This rite, which always took place in the spring, was a necessity, as generally 25–35 percent of the fields lay fallow every year. The other aspect was the assembly of as many farmers as possible, a difficult task since the rural population was highly mobile, labor was becoming scarcer, and peasant settlements were highly dispersed over the landscape.

It would be a mistake, however, to assume that rice paddies were the only or perhaps even the predominant means of livelihood. For thousands of years, residents of the archipelago had survived as affluent foragers, hunting, fishing, and gathering nuts and tubers. Moreover, slash-and-burn farming was a common alternative to rice farming because it took place in the mountains and could not be effectively taxed. Peas-

➤ THE SPRING HUNGERS

Most of the populace of Japan suffered from chronic malnutrition throughout the ancient period despite the introduction of wet-rice cultivation to Japan around 900 BCE. To be sure, yields from paddy land were relatively high, but farmers struggled to maintain the land in continuous production because of drought, blight, insects, and floods. Other peasants, unwilling to subject themselves to the taxation on wet-rice paddies, simply abandoned their lands and fled to the hills to live off game, fish, nuts, and tubers. Moreover, frequent epidemics afflicted a populace with no immunities, killing high percentages of the cultivator class and leaving fields barren. Even when cultivators tilled the same land continuously, crops failed about once every three or four years.

Fortunately, historians have records for the prices of various grains during the famine year of 762. As one might expect, these data show that the supply of rice, barley, and wheat was highest immediately after the autumn harvest. As the seasons progressed, storehouses became empty. By the spring (February–March), prices for all grains skyrocketed. The supply seems to have been so low in the summer of 762 that no data survived to indicate prices. This condition, which continued until at least the sixteenth century, has come to be known among historians of Japan as the spring hungers. Even in the best of times, diet was just barely adequate to sustain the population.

—William Wayne Farris

ants also planted dry crops such as wheat, barley, millet, soy beans, and buckwheat. A dry field yielded only about 25–35 percent of a good rice paddy, but the government did not systematically tax unirrigated land. Dry cropping also required much less labor than rice farming did. In essence, despite the importation of rice agriculture as early as 900 BCE, Japan was ill-suited to becoming a rice-based agrarian society because of the small amount of flat land, poor irrigation technology, and the generally acidic nutrient-poor soil. The long, slow transition to a fully agricultural society would take at least another half a millennium.

Thanks to the work of archaeologists, scholars have uncovered considerable details about

material life in the countryside. Peasant huts were pit dwellings made entirely of lumber and thatching grasses and straw, with the dirt floors beneath ground level; they were cold, dank, and prone to fire. Clothing was sewn from hemp or ramie plants and would have been cold and scratchy to the skin. Toilets were either nonexistent or consisted of a hole with two boards upon which the person squatted. Diet consisted of the aforementioned grains and probably included brown rice, meat, nuts and tubers, and fish. Even in the best of times, caloric intake was just barely enough to sustain the populace. Farmers harvested only one crop in the fall, and food often ran out in the spring or summer, a phenomenon known as the spring hungers.

Diffusion of Asian Crops and Livestock to the Mediterranean Region and Africa

In the global history of human agriculture, at least five great series of events are prominent:

- 1) The Neolithic Revolution, during which most domestic animals and many crops were domesticated, beginning about 10,000 years ago. This was the effective beginning of agriculture.
- 2) The Muslim Agricultural Revolution, involving the diffusion of crops and livestock from India and Southeast Asia to the Mediterra-

nean region and Africa south of the Sahara during the Early Medieval Age.

- 3) The Columbian Exchange beginning in the late fifteenth century CE in which the crops that had been developed by the Native Americans spread to all the civilizations of Europe, Asia, and Africa.
- 4) The Agricultural Revolution of the eighteenth and nineteenth centuries CE.
- 5) The post-World War II Green Revolution.

The following centers on the second of these series of events, focusing on the diffusion of crops and livestock, which occurred before and during the Muslim Agricultural Revolution.

The spread of livestock to the Mediterranean region and Africa during the first millennium CE, while mainly consisting of Southeast Asian animals, also included the camel from the Arabian Peninsula and the silkworm from China. Of the Southeast Asian animals, at least one, the chicken, began its spread to the Mediterranean world at the beginning of the first millennium BCE, but its appearance in Africa south of the Sahara did not occur until the early centuries CE. Another animal from Southeast or South Asia, the Asian buffalo, also known as the water buffalo, may have spread to Egypt early in the first millennium CE, but it was not known in the Maghreb or Mediterranean Europe until the seventh century.

The new crops brought to the Mediterranean region and/or Africa south of the Sahara during this time included cotton, sorghum, sugarcane, rice, taro, lemons, limes, other citrus fruits, spinach, bananas, plantains, eggplants, and certain types of melons.

The spread of camels from Arabia to North Africa and the Sahara Desert began in the last centuries BCE but had its greatest impact in the middle centuries of the first millennium CE. Camels were brought across the Red Sea to Somalia in the last centuries BCE where the Somalis as well as the Beja tribesmen quickly adapted themselves to camel culture and camel nomadism. At the same time, camel herding spread to Egypt and to the Berber tribesmen of Libya and the Roman territories of North Africa. Some Berber tribesmen, the Tuareg, also developed camel nomadism. They ad-

vanced with their camel herds to every area of the Sahara Desert, subjugating the farmers of the Sahara oases and reaching the Sahel south of the great desert. By the beginning of the early medieval period (300 CE), the camel-date complex, in which camel nomads and date palm-cultivating oasis dwellers had established a symbiotic trade relationship, was ubiquitous throughout the Sahara. Within another century, Berber herders inaugurated a thriving camel-borne trans-Saharan trading system.

The buffalo, sometimes called the river or water buffalo, spread from North India through Sassanian Persia to West Asia by 300 CE. Although the Egyptians probably knew of the buffalo by 300, there is no evidence that it became common in the eastern Mediterranean region until 600 CE. When the Muslims conquered North Africa, they brought the buffalo with them and then introduced it to Andalusia in the early eighth century. The Aghlabids introduced it to Sicily in the ninth century, but it was not until the mid-eleventh century that the mainland Italians became acquainted with the animal. The Muslims and the Italians both used the buffalo as a draft animal, but they prized it for its rich milk as the raw material for some distinctive cheeses.

The diffusion of Southeast Asian crops to Africa south of the Sahara and the Mediterranean region involved two different processes that were not exactly simultaneous: the Austronesian migration from Indonesia to Madagascar and the diffusion of crops west from India consequent to the creation of the Islamic caliphate.

The people who settled Madagascar began sailing across the Indian Ocean to East Africa at about the beginning of the Common Era. They traveled along the southern coast of Asia, first to Sri Lanka and southern India, and then along the coast of South Arabia to what is now known as Somalia and south to modern Tanzania. Subsequent voyages continued from Tanzania to Madagascar, which had previously been devoid of humans. The Austronesians brought their crops in their outrigger canoes. They established these crops on Africa's east coast as well as in Madagascar. Rice was the major crop that they brought, but coconuts, taro, sugarcane, cotton, new vari-

Sugarcane fields in the Nile River valley, Egypt. Sugarcane was introduced to Egypt during the Muslim agricultural revolution. Since it is a summer crop that demands much water, and since the Nile River was normally low in the summer, growing sugarcane in Egypt required heavy investments in irrigation systems. (Espixx)

eties of sorghum, Asiatic yams, and, importantly, bananas and plantains were also brought on the Austronesian craft. In addition, the chicken crossed the Indian Ocean with the Austronesians. The commerce between Indonesia and Madagascar was two ways and may have continued until the fourteenth century CE.

The Southeast Asian crops introduced by the Austronesians became a very important addition to the agricultural portfolio of East Africa and by the eleventh century had spread across the continent to the Atlantic coast and into West Africa. For interior and West Africa, bananas and plantains were the most important of these crops. Where the rainfall is sufficient, bananas and plantains are easy to propagate, requiring only the insertion of a stem cutting into the soil. Bananas and plantains are high in calories and are nutritious. In much of sub-Saharan Africa they became the staff of life, the principal crop. Indeed, in some African languages, the word for bananas and plantains and food in general are the same.

A consequence for sub-Saharan Africa of the diffusion of Asian crops, particularly bananas and plantains, was that it made possible the increased production of high-caloric food per unit of land. This allowed populations to grow and population densities to rise. More cities grew, and new states were created.

The Muslim Agricultural Revolution, of which the diffusion of cultivars from India to the Mediterranean was a central part, was a consequence of the emergence of the Islamic empire with its unification of areas producing diverse crops. The Islamic empire established the largest zone of peace and security that the world had known until then. In this zone a Pax Islamica prevailed in which commerce and people moved from Spain to Sind (northwestern India) and from the Malabar Coast to the Mediterranean Sea. Muslim merchants (in this period, mostly Arab), military men, administrators, and scholars collected plants in their far-flung travels, returned to West Asia to retire, and established gardens to raise these exotic crops. Thus, rice, sugarcane, spinach, eggplants, mangos, taro, sorghum, bananas, lemons, and other citrus fruit were planted in gardens from Spain to Persia and from Morocco to Oman in the early Islamic centuries. They could be grown in gardens on a small scale with a high investment in labor, but raising these new crops on a larger scale required a drastic change in Mediterranean agriculture.

Most of these new crops, except spinach and citrus fruits, were hot-weather crops that required copious amounts of water. They were adapted to India and Southeast Asia, where the summer monsoons provided just the right milieu for them. But in the Mediterranean region, wheat and olives, adapted to dry summers and wet winters, were the rule. To successfully propagate the hot-weather Southeast Asian crops in the Mediterranean region required a high investment in irrigation systems. By the ninth century old irrigation systems were revived, and new ones were constructed in Spain, North Africa, Sicily, Syria, Iraq, and the rest of the Islamic world. This allowed Islamic agriculture to be much more productive, to harvest crops in two seasons rather than relying only on the cool-weather winter crops. Also, the diffusion of Southeast Asian crops throughout the Islamic world resulted in a much more diverse and exciting culinary palette.

European Rural Economy

Economic conditions in Europe began to deteriorate during the late third century when the Roman empire faced political upheaval, barbarian incursions, and population decline. The Romans responded with increasingly rigid state control of the economy, leading to a decline in the role of towns in the economy. As a result, the economy of early medieval Europe came to be primarily agricultural. Commercial activity fluctuated throughout the period but never disappeared.

The agrarian economic structure most closely associated with the Middle Ages was the manor, an agricultural structure that emerged between 400 and 800. By the ninth century manorial estates dominated the eastern half of Gaul, Italy, the Rhineland, and southern and central Germany. By the end of the tenth century the manorial model dominated England and Denmark. However, it is important to note that the medieval agrarian economy was not monolithic. Many types of estates existed, and these varied with geography, population density, climate, and soil conditions. For example, in southwestern Gaul and on the Saxon plain, manorial estates never completely dominated the economy. Small and large estates existed side by side along with free holdings called *allods*. Friesland as well as parts of Holland, Norway, and Sweden never had a manorial system. Because many more records survive from manorial estates, any discussion of medieval agriculture must focus on the system about which historians have the most information.

Manorial estates generally consisted of three parts: the lord's holding or demesne, the tenants' holdings, and often a common holding such as a pasture or forest. The lord was a local strongman whose ancestors had been powerful Germanic or Roman nobles or governmental officials. The peasants descended from slaves or freemen who had given over their land and free-

dom in varying measures to the lord's ancestors in exchange for protection and security during the politically and economically uncertain times after the decline of Roman power in the West.

Custom and the traditions of the estate determined the lord-tenant relationship. In general, the lord or his agents directed the work and provided the management needed to run the estate. The peasants, often referred to as villeins or serfs, worked their own parcels and provided day-to-day labor needed to farm the demesne as well as rents in the form of payments in kind. Beyond this, the specific obligations between lord and peasant varied from one manor to the next and depended on the original deal made between their ancestors.

The medieval agricultural economy produced a myriad of goods. Each manor existed primarily as a self-sufficient unit and produced everything it needed. In addition to such staple cereal crops as wheat, barley, and rye, peasants grew spelt (a grain resembling wheat), oats, buckwheat, and millet. In gardens they grew turnips, peas, lentils, beans, and onions, and to support the expanding textile trade they grew dyer's weed, woad, madder, saffron, and teasels. Flax and hemp were important crops as well. Southern Europe grew olives and grapes, and temperate zones grew fruit trees, including apple, pear, plum, cherry, and fig, as well as walnut, hazelnut, and chestnut trees. Pigs roamed forests, feeding on acorns and other nuts, and provided most of the meat. Medieval estates also kept cattle for traction, meat, and dairy and sheep for wool, meat, and dairy products.

By the tenth century the population of Europe began to grow. The rapid clearing of forests and expansion of arable land that occurred in this period suggest that there were more people to feed. The Romans passed down sound agricultural techniques, including knowledge of intensive weeding, crop rotations, and the need for fertilizing land with manure, ash, and green manure crops. Some of this knowledge went into disuse, but such new innovations as the heavy plow and open field systems made it possible to open up heavier soils of northern Europe to feed more people. The increase in arable land also increased the availability of pasture and fodder crops, which led to a better balance

between cereal crops and animal husbandry.

Historians have only a few references in chronicles and a sparse archaeological record upon which to base conclusions about the economy of post-Roman Europe, but it is generally accepted that trade and commerce declined during the early Middle Ages, and the West suffered more in this decline than did the eastern half of the Roman empire, driving Europe to an increasingly rural and agricultural economy. Historians believe that the empire had long suffered from a trade imbalance, and after 300 the problem became more pronounced. Eastern provinces produced commodities, silk, spices, jewelry, and grain, all things that the western provinces wanted, while the west, with its agricultural economy, had little more than slaves to offer in return. The western provinces had to pay for everything with currency, so gold flowed west to east and never came back into the western economy. This apparent trade deficit, combined with fifth-century barbarian invasions, the fall of the western Roman empire in 476, and the advance of Muslim power in the seventh century, led historians to one of the most hotly debated historical arguments of the twentieth century. What was the cause of the economic decline of Europe in early medieval times, when did it occur, and how severe was it?

In general, historians agree that trade and commercial activity decreased during the late Roman period and then fluctuated throughout the early Middle Ages. Trade declined during the fourth and fifth centuries, revived in the sixth and early seventh centuries, diminished again at the end of the seventh century, and remained at low levels throughout the ninth century. During this period, economic activity shifted to the local level and became increasingly rural. Small towns and manors produced goods to meet local needs. Most craftsmen and farmers did not produce for the market but instead worked to meet

Chronicle of the Months, an early Carolingian manuscript showing agricultural labors, ninth century CE. (Erich Lessing/Art Resource, NY)

► INTERREGIONAL TRADE

Local trade and trade within the regions of Europe played an important role in the economy of early medieval Europe. Historians often treat the economies of northern and southern Europe as separate, but they were far from unconnected.

Nearly every locality had a market that served the area's needs. Markets occurred frequently, perhaps weekly, and specialized in cheap or perishable commodities. They offered people a place to buy or trade for goods that they could not produce themselves or that they produced in surplus. Local markets had to be within walking distance so that a peasant had time to walk to the market, conduct business, and walk home. Regional markets met less frequently and served as a meeting point for merchants to sell off or trade items they had accumulated in abundance and to restock the items in which they specialized. By the twelfth century some large regional markets eventually evolved into fairs, which met two or three times a year and served as an outlet for large business transactions.

By way of this system of markets, goods moved all over Europe. Southern areas sent wine, olives, spices, silk, and other luxury items to the northern parts of the continent. The northern provinces sent back indispensable items such as grain, butter, cheese, fish, timber, metals, salt, and their one luxury item, furs. Advances in agricultural technology allowed the Frankish kingdoms to produce a surplus of foodstuffs they could trade to areas that could not feed themselves such as Scandinavia, Frisia, and eventually Flanders.

—Kevin Hill

the needs of their self-sufficient village or manorial economy.

However, it would be a mistake to believe that all trade ceased or that only an agrarian economy persisted. Sixth-century documents refer to Syrian and Jewish merchants in Francia, and at the end of the sixth century Marseilles remained a trading center and entry point to the West for goods from the East. Many scholars have pointed to these and other facts, including evidence indicating the continued use of coins in the West, to conclude that trade in various

commodities continued between East and West throughout the early Middle Ages.

The Three Sisters and the Spread of Agriculture in North America

Archaeologists have dated the cultivation of maize (corn), beans, and squash to at least 7000 BCE. They believe that maize originated from a wild grass or corn in the Tehuacan Valley of Mexico by that date. Early maize had small cobs with only a few kernels on each one. Early indigenous Americans, however, recognized that they could plant seeds and receive a harvest after the plants matured. They quickly recognized that selecting the best seeds from the plants that had the most favorable characteristics would result in better harvests. Thanks to this seed selection, maize along with beans and squash became the most important part of most indigenous Americans' diets.

The agricultural lifestyle that resulted from growing maize and the other crops changed indigenous American society. They moved from a hunter-gatherer culture to one that was more sedentary. A more dependable food supply also resulted in an increase in population. Food surpluses allowed some individuals to take on new functions not connected with simply obtaining food to survive. Religious and civil leaders emerged. Cities developed with denser populations than ever before.

Seed selection resulted in the development of various types of maize, beans, and squash. Each variety had characteristics that were useful in certain circumstances. Corn varieties in-

cluded flint corn, which had larger yields and grew better in cooler climates. Flour corn had a soft starch center that could be easily ground into flour for making dough. All parts of the corn plant were used by the indigenous Americans. They found that the leaves were high in sugar, and these were chewed by the Maya. Immature cobs were cooked and eaten whole as vegetables. Even the silk on the cobs was dried and used as a seasoning.

Varieties of beans that were developed included black, lima, and runner beans. Beans were cooked or dried and ground into flour. When domesticated beans spread to the Southwest, farmers there used seed selection to develop varieties that could withstand dry heat better. Beans provided the amino acids lysine and tryptophan lacking in corn. Squash varieties included pumpkin, acorn, zucchini, and crookneck. Squash was not as important to the diets of indigenous Americans but did provide nutrients.

By 1500 BCE farmers in the Southwest were growing maize with seeds obtained through trade. Production was limited until around 300 BCE, when they developed varieties that grew better in dry conditions. The Hohokam people dug miles of canals to carry water to their maize, while the Anasazi developed a flood irrigation system to take advantage of seasonal rainfall. Other indigenous Americans planted their crops in crevices or at the foot of cliffs, where water collected.

Maize reached the Mississippi River valley around 200 CE but was not widely grown until around 800 CE. It allowed the development of the Mound Builders civilization in that region. The surplus food produced by maize and the other crops permitted the development of a class of elites who ensured a distribution of food in lean years and helped keep the social order. Other indigenous American peoples in the Southeast and Northeast adopted a more settled lifestyle when they began growing maize, beans, and squash around 1000 CE. They cleared fields and planted all three crops together. They found that all three did better when grown together.

Maize, beans, and squash became known as the Three Sisters because indigenous Americans regarded them as so important and essential to

THE INTERLINKED THREE SISTERS

Cherished as the Three Sisters by indigenous North Americans, corn (maize), beans, and squash support each other as well as their human cultivators. Grown together in the same plots, these plants provide mutual aid. Maize, with its heavy demand for nitrogen, depends on beans, which provide nitrogen from the air and in turn use the corn stalks to climb toward the sun, while squash plants, with their big leaves, smother weeds that otherwise would rob the three crops of nutrients.

—Tim J. Watts

their culture. They assigned religious meanings to each one, especially maize. For many tribes, their creation stories included an important role for maize. Some, such as the Iroquois, believed that the three crops should be grown together and dried together to preserve them. They represented a balance that was an ideal in life.

Mesoamerican Agriculture

Agriculture in Mesoamerica was central to the development of civilizations in the region. The development of edible plant species that could produce significant harvests allowed the people of Mesoamerica, especially the Maya, to create complex societies with specialization among professions and enough time for higher learning. Improved food production also led to an increase in the total population in the region and the building of infrastructure to improve the quality of life. The success of Maya agriculture between 300 and 1000 CE resulted in a Classic Period, and the end of that period may have been the result of agricultural failures.

Mesoamerican agriculture produced more edible plants than that of any other region, with the exception of China. By the time Europeans arrived, 88 species had been domesticated and were used as food products. The cultivation of basic food crops, especially maize, beans, and squash, spread throughout the region as well as beyond during this time. Mesoamerican farmers displayed a great deal of talent for nurturing favorable genetic mutations. Wild squash, for example, were first gathered over 9,000 years ago. The seeds, which are rich in edible oil, were the only part consumed originally. The flesh of the squash was thin and bitter. Prehistoric Mesoamerican farmers recognized that by saving seeds from plants with the most favorable characteristics, they could gradually develop a more useful species. By 4000 BCE, they had a number of domesticated squash species that could provide nutrition. Maize was also domesticated at an early date. By 2000 BCE, it was being grown throughout Mesoamerica and was a basic staple. Genetic manipulation by early farmers increased the yield many times but produced a plant that could not survive without human intervention. Other important plants that were domesticated by the Mesoamerican farmers included trees such as the cacao.

Agriculture in Mesoamerica was a complex process that required large numbers of people working together. As a result, anthropologists argue that it helped in the development of ever more complex societies. The type of agricultural system and the techniques used depended upon the climate and other conditions.

One of the earliest systems of agriculture that remained in use in tropical forest areas of Mesoamerica is the slash-and-burn system, which became known as milpa agriculture. During the dry season, the vegetation on a plot of land was cut and left to dry. When the rainy season started, the vegetation would be burned. The ashes provided nutrients for the crops planted in the field. A clearing or field would be used for 2 to 3 years and then abandoned for the forest to reassert itself. This fallow period often lasted up to 20 years. Advantages of the milpa system included no need for fertilizers and a decline in the number of insect pests in a field. The drawbacks in-

cluded a need for large amounts of virgin forest that could be brought into cultivation. As populations grew, the amount of land available declined, and fallow ground was not allowed enough time to restore its fertility.

Typical crops in Mesoamerican milpa agriculture included maize, beans, and squash. The beans used the corn stalks for its vines while adding nitrogen to the soil. Maize required large amounts of nitrogen and provided stalks for climbing bean vines. The squash helped shade the ground and prevent the evaporation of moisture. Many other types of crops were planted in the same fields at the same time. Cotton, for example, was cultivated by the Maya and became an important trade good. The cotton cloth was woven in complicated weaves and was richly embroidered and colored. Fixed lengths of cotton cloth were traded like currency among the people of Mesoamerica. To achieve some return from the fields being left fallow, trees, such as avocado, were planted. Most families farmed several plots at the same time, with each at a different stage in its useful career. The clearing required periods of intensive manpower use, promoting greater social organization and control. Mayan rulers were able to marshal their subjects successfully to clear the land as needed during most of the Classic Period.

Other agricultural techniques that were used by Mesoamerican farmers depended on the organization and use of large numbers of people, especially to provide an adequate supply of water to crops. Examples of these techniques include the irrigation and terracing of fields. Many Mayan fields cultivated between 300 and 1000 CE show signs of these systems. In terracing, sloping fields were built up into a series of steps. Terracing prevented soil from washing away and crops from being damaged. It also helped to retain moisture in the field. Terracing required the creation of retention walls, which was done through brush or stone walls. Many walls were the product of generations of farmers. Mayan farmers also depended on raised fields to grow crops. Where the ground was suitable, canals were dug throughout a field, and the removed soil was placed between the canals. Water flowed through the canals to irrigate the fields.

A year-round supply of water was provided by reservoirs or by diverting streams. Archaeologists have found evidence that the fields could be completely flooded during different times of the year to help control pests.

Irrigation depended on the artificial supply of water to fields in regions where rainfall was seasonal. In most of Mesoamerica, rainfall was most common between May and December. The porous limestone bedrock of the region tends to drain away water that falls, requiring human intervention to provide water year-round. Reservoirs and canals were used to accumulate the water and to bring it to the fields. Most Mayan farming may have been concentrated in the bajos, forested wetlands where the most water could be found. These bajos would have been the centers of agriculture and supported the Mayan cities nearby. Like terracing, irrigation required large amounts of human labor. The result, however, was greater food production, encouraging a growth in population.

The most varied and intensive food production was in home gardens. These were small plots near the residences of the inhabitants. Plants in the home gardens were those that required the most intensive attention through weeding, watering, or transplanting. They were also home for the plants whose products were needed in small quantities on a regular basis. Security for gardens against human and animal predators was important, and they were often enclosed by stone walls. Yields were higher on home gardens than on other agricultural areas. Farmers were aware that fertilizer such as bat guano or lime could increase yields. They also used waste water from the homes to water the gardens as needed. Products from the home gardens included medicinal plants, ornamental plants, and spices. Fruit and nut trees, including avocados and cacao, were prominent in home gardens. In some Mesoamerican societies, fields were owned and worked communally, but home gardens were always under the control of the resident. They were often the source of individual wealth or status. While products from larger fields provided the food needed to sustain life, the gardens provided luxury goods for sale or trade.

The Agricultural Economy of the Andes

The economy of the Andes between 300 and 1000 CE was based upon agricultural products. Most communities strived to be as self-sufficient as possible. Very few essential products were not produced locally. As a result, most Andean societies lacked hard currency and a merchant class. Instead, they bartered for goods and commodities.

The key factor of life in the Andes was the influence of geography. Different elevations had radically different environmental conditions, which determined which crops and products could be produced. At the higher elevations, herding was the most suitable form of agricultural production. At lower levels, where moisture was more common, different kinds of crops were grown. Farmers in the Andes recognized the need to diversify the crops they grew. By doing so, they could avoid disasters from pests or bad weather that would destroy one type of crop. To raise different foods, control over ecological niches was necessary. By establishing growing areas at different elevations, which were relatively close to each other, Andean farmers could grow a variety of crops. Not only were they protected against the failure of one type of crop, but their diet was more varied and nutritious.

Crops grown by the Andeans were the result of centuries of domestication by their predecessors. Early farmers recognized that they could improve the production of crops by planting seeds from the plants with the most desirable characteristics. Careful nurturing created species that still remain important to modern agriculture. Potatoes were the most important food

Common Andean dried staples, including dried corn, freeze-dried potatoes, and lima beans. (iStockphoto)

crop grown in the Andes. Other crops included peanuts, lima beans, squash, and chili peppers. At lower levels, important amounts of maize, cacao, and different kinds of fruits were grown. Andean farmers also raised cotton and gourds for manufacturing useful items.

Protein was provided by meat from llamas and alpacas. These camelids had been domesticated centuries before, and large herds thrived at higher elevations. Llamas were also used as pack animals since they could carry up to 90 pounds. Both llamas and alpacas were valued for their wool. Llama wool was used for ropes and sacking, while the finer wool of the alpaca was woven into clothes. Further protein was provided by guinea pigs, raised by Andean farmers. Around lakes, such as Titicaca, fisheries provided additional sources of protein.

Because each community valued self-sufficiency and they lived on the edge of subsistence, the Andeans developed methods of preserving food from years of surplus. The most famous is the freeze-drying of potatoes. They also dried llama meat, which they called *charqui*, possibly the source of the English term “jerky” for dried meat. Surplus food was stored in state warehouses and issued to citizens when needed.

Most Andean states during this time resembled a socialist society whereby private ownership was rare. Fields were allocated to each household according to their anticipated needs and ability to work the land. Seed and farming tools were owned by the state and distributed ac-

cording to need. When poor harvests occurred, surplus food was redistributed from state warehouses. Because a monetary system did not exist, a system of labor tax was used, with each person owing service to the rulers. On sloping mountain fields, this labor might include building terraces to prevent erosion. In the dry coastal lowlands, a system of canals was constructed to bring water from the few rivers and springs to the fields. Labor was carefully monitored. Those who were away from home, either in the army or working in mines, had their fields tended by others who lived in the same political unit.

The success of the Andean agricultural economy and the surpluses it produced allowed a degree of specialization and the emergence of elite classes who did not work the land. These included priests and leaders for a religious system that was common through most of the Andes. This system included many shrines of varying importance. Most shrines had their own lands assigned to them, along with the people required to work the land. Other members of the elite class included hereditary nobility and the rulers of the Andean states, all of whom had lands and workers assigned to them.

Some agricultural products were in great demand but could not be grown in Andean highlands. Groups of colonists were sent by their rulers to locations where these products could be grown to create new settlements. Such products included cacao, fruit, and marine products. They were the center of a system of long-distance trade, carried mostly by caravans of llamas. Because this trade was not conducted for profit, it did not lead to the development of a merchant class. A network of roads and bridges, along with rest stations at regular distances, was created to facilitate this redistribution of agricultural products.

■ Introduction: Early Medieval Industry

The most widespread form of industry in all early medieval societies was handicraft manufacturing. The largest share of early medieval handicraft manufacturing was done by families in the home for home consumption or by village craftsmen for use within the village or its vicinity. Milling of grain, the making of beer and bread, and the processing of meats, cheeses, and other dairy products were all home or village industries, as was much preparation and weaving of linen, hemp, wool, and similar textiles (or cotton in parts of the Americas). Many villages had their potters, house builders, and metalsmiths, and many homes made candles and wooden tools that fabricated almost all of the industrial products used by the average villager.

In the larger towns and most of the cities, much of these handicraft industries were carried out in specialized shops with a master and a few subordinate craftsmen. In India, where craft specialization was very highly developed, castes, which in these centuries were very close in function to guilds, controlled and conducted most crafts, a consequence of which was that India produced some of the finest manufactures of the age. For many centuries, Indian weavers were renowned for the fine cotton textiles they produced. In West Africa too, many crafts, particularly metalsmithing, was controlled by caste guilds.

One of the most active industries in most early medieval societies was the manufacture of weapons and armaments. Swords, spears, bows and arrows, and shields were the most common weapons. Indian steel swords, made by the secret Wootz process, were widely sought throughout Eurasia. Only toward the end of this era were the metallurgists in Damascus and Toledo able to manufacture blades with such keen edges. The Indian steel longbow made Indian armies formidable until the end of this era. The Chinese excelled in manufacturing crossbows, which they were able to mass-produce.

Navies and shipbuilding also called for industrial production. Most effective naval powers—the Byzantine empire, the Arab caliphates, the Tang dynasty, and, late in this era, Venice and

perhaps other Italian cities—had closely supervised government shipyards.

Metallurgy, particularly iron manufactures, was a very important industry. In certain periods, the making of iron tools and weapons was a state monopoly in China. The Chinese developed a method of mass-producing relatively inexpensive but brittle cast iron. The abundance of Chinese iron tools is sometimes credited with the exuberance of the Chinese economy in the early medieval age. In India, the metalworking guilds also produced abundant metal for tools and weapons. In Teotihuacan, much of the prosperity of the city rested on the skill of the craftsmen who carved obsidian tools and weapons for much of Mesoamerica.

Although the making of cotton cloth probably originated in India, which maintained its preeminence in that industry, demand for cotton textiles was enormous in the Muslim world, and cotton-weaving establishments sprang up in many Muslim cities. Cotton weaving was also important in the Andes as well as in Mesoamerica and was beginning to spread in Africa.

Porcelain was a leading industry in China during the Tang dynasty and developed an important export trade, particularly to Muslim lands as far west as the Swahili coast, and porcelain-manufacturing establishments were becoming large enterprises. Papermaking, another industry of Chinese origin, had by 800 spread to the Muslim world, and within less than a century many Muslim cities had a papermaking establishment. It would require another three centuries before the process leapt the cultural barrier to Christian Europe.

Before 1000 CE, industrial production in Europe was still in its infancy. It would be several centuries before Europe would catch up with the more highly developed industrial regions of the Muslim world, India, and China.

China, the Economic Powerhouse of the Early Medieval World

The great wealth and power that China accrued during the Han dynasty (206 BCE–220 CE) came as a result of significant technological advances such as the widespread use of iron, the acceleration of communications with an improved network of roads, and the extension of military power. The Chinese economy declined with the fall of the Han dynasty and had grown little during the period of division (220–589 CE). It rebounded under the Northern Wei (386–534), Sui (589–618), and Tang (618–907) dynasties.

The period of relative peace extending from the late fourth century to the fall of the Tang allowed for an impressive growth in population, production, trade, and culture. There were significant advances in technology and agriculture, the building of major canals, and a vast expansion of foreign trade. Furthermore, the implementation of the equal field system, which allotted several acres of cultivable land to each adult male, provided a high degree of financial stability. Commerce grew rapidly, and a highly developed money economy emerged. There was a concurrent rise of overseas trade from the start of the eighth century between China and South and West Asia. There also emerged a large land-owning gentry class that remained in power from the Tang through the end of the Qing dynasty in the early twentieth century.

The rise in prosperity came with the unification of China under the Sui. The last ruler of the Sixteen Kingdoms had already unified northern China in the late sixth century. The Sui rulers brought order to China with the introduction of a comprehensive new legal code, the establishment of reforms in local administration, and the continuation of the equal field system begun by earlier kingdoms. A reorganized and highly efficient bureaucracy brought in increasing tax revenues, while price-regulating granaries brought

in grain in times of glut and sold it cheaply in times of poor harvests.

The second Sui emperor, Yang Di (r. 605–618), used the greater resources available for several major projects, the most grandiose of which was the construction and extension of the Grand Canal from Hangzhou north across the Yangzi to Yangzhou and then to Loyang in northwestern China. By 609 the canal was extended to the regions of Beijing and Tianjin. These canals, when combined with local streams and lakes, made possible the barge transport of food and other commodities of the lower Yangzi to fortify the northern frontier as well as to feed the major cities of Chang'an and Loyang. The canal between Hangzhou and Chang'an can be called the first Grand Canal of China, in contrast to the more modern canal built during the period of Mongol rule between Hangzhou and Beijing. These two grand canals had the same primary purpose to supply food from the south to the capital city and to the border armies that defended them.

The Sui dynasty, however, came to a very premature end after the failed reigns of Sui Yangdi and Qin Shihuang. Yang Di made an unfortunate attempt to invade Korea. His overwhelming defeat exhausted his resources and brought widespread rebellion across China, which led to the collapse of the dynasty in 618.

The new Tang government was more prudent in its administration of the country, but it also benefited from the advances implemented under the Sui. They inherited the huge capital city of Chang'an (with a population of 2 million by the 700s) and the secondary capital at Loyang. Later in the seventh century when armies swept northward to occupy Korea, southward into Vietnam, and westward into central Asia, China opened the way to the oasis trading cities of the Silk Roads and West Asia. Chang'an, located at the terminus of the Silk Roads, became a great international metropolis, perhaps one of the largest, wealthiest, and most cosmopolitan cities in the world.

The government of the Tang dynasty was far wealthier than the earlier Han dynasty. Important advances in agriculture and government administration were responsible for part of this gain, but of greater importance was the signifi-

cant population growth in the Yangtze River valley since the third century CE. The chief agriculture area for China was no longer the dry wheat and millet land of the Wei Valley and the North China Plain but rather the rich rice paddy fields of the Lower Yangtze region.

There was a vast expansion of international trade during the Tang period. The reopening of the Silk Roads stimulated a huge demand for Chinese goods such as silk, lacquer, and porcelain in the Middle East and Persia. In addition, tea became a major export item, although tea consumption had become popular in China during the Northern and Southern dynasties (420–589). Chinese maritime trade from such ports as Guangzhou (Canton) extended to Japan, India, the Persian Gulf, and the Red Sea. Guangzhou emerged as a thriving international port with a large expatriot population.

Salt and iron monopolies became important sources of revenue for the Tang state. During its early years, Tang rulers allowed the private manufacture of salt and iron, but in 758 Emperor Tang Suzong established a salt monopoly. The government introduced a monopoly of iron and mines in 780 as well as an intermittent monopoly on the production of liquor in 782.

In addition to the expansion of trade and production, developments in science and technology flourished during the Tang dynasty. New products included matches, the double-action piston pump, cast iron, the iron plow, the horse collar, the multitube seed drill, the wheelbarrow, the suspension bridge, natural gas as fuel, the propeller, the sluice gate, and the pound lock. Many of these innovations paved the way for the great wave of prosperity during the Song dynasty (960–1279).

The Tang began a long period of decline starting in the middle of the eighth century. A series of weak rulers combined with expensive military overexpansion and defeats in central Asia significantly weakened the state. The bitter rebellion led by An Lushan swept China between 755 and 763, bringing devastation to both cities and valuable farm land before the Tang government could restore order. The administration, however, never recovered the power it had possessed before the rebellion. Increased military weakness and successions of invasions from

The Grand Canal in China was constructed by the second Sui emperor, Yang Di, during the seventh century CE. China's early medieval prosperity was based to a large extent on its advanced system of inland transportation. (Yory Frenklakh)

outside China proper led to the final collapse of the empire in 907.

Economic Development in India

Indians created sophisticated institutions and mechanisms in trade, mercantile organizations, shipping, banking and currency, and taxation during the era 300 to 1000 CE. The merchants and craftsmen of classical India were generally organized into *śrenis*, or guilds. These must have existed from the beginnings of settled Indian society, since they are mentioned in the later Vedas and the Jatakas (stories of the lives of the Buddha and his aides). Each such guild was headed by a chief executive (*mukhya*) assisted by advisers. They had the power to control

THE BAZAARS OF CLASSICAL INDIA

Indian commerce showed its flamboyant best at the bazaars, which were a highlight of most towns and cities. City markets could be massive cornucopias of the wealth of metropolis, countryside, and even foreign parts. A large bazaar would contain separate rows, even separate sections, for the varied spices, bolts of gleaming cotton cloth, heaps of fruits and vegetables, and handicrafts of wood, ivory, metals, and so on. Other shops lined major streets. The stereotypical shopkeeper (often called a *bania* or *banyan*), squatting or sitting cross-legged in his stall, has probably changed little over the centuries.

The bazaar of Sagala (Sialkot) in the northern Punjab, a city with “thousands of magnificent mansions,” streets filled with elephants and horses and carriages, and “frequented by groups of handsome men and beautiful women,” is described in a Buddhist classic, *The Questions of King Milinda*: “Shops are there for the sale of Benares muslin, of Kotumbara stuffs, and of other cloths. . . . [S]weet odours are exhaled from the bazaars, where all sorts of flowers and perfumes are tastefully set out. Jewels are there in plenty, such as men’s hearts desire. . . . So full is the city of money, and of gold and silver ware, that it is a very mine of dazzling treasures. And there is . . . food and drinks of every sort, syrups and sweetmeats of every kind.”

Even this is surpassed by the account of the great Tamil epic, the *Shilappadikaram* (*The Ankle Bracelet*), of the markets of Madurai of the fifth century CE. Ships laden with incense, silks, sandals, and camphor were driven up the river Vaigai and into the harbor. Kovalan, hero of the epic, was a small-town youth dazzled by his first sight of the great city of Madurai. He entered the jewelers’ special street, where “shining diamonds were sold, without flaw or stain or crow’s-foot,” and “cloudless green emeralds, perfect in form and luster,” and “heaps of white and pink pearls.”

“In the street of the cloth merchants Kovalan made his way through piles of bales, each containing a hundred lengths, woven of cotton, hair, or silk. There was a street for grain merchants, busy with their balances, measures, and bushels. Bags of grain and pepper were to be found there in all seasons.”

—Edwin Hirschmann

prices, productivity, standards of work, and conditions of labor. Apparently they also had the power to punish violators of their edicts by reprimands, censure, seizure of goods, or even banishment. Such internal judgments were usually respected by kings and their courts. The guilds superintended the artisans through their training, with four ranks generally recognized: apprentice, advanced student, expert, and teacher. Finely made goods were a source of pride, and craftsmanship was considered a gift from the gods that superseded one’s caste restrictions.

In the classic *varna* (caste) structure, the merchants and shopkeepers occupy a middle rank, distinctly lower than the Brahman priests and the warriors/nobles, but they played a respected part in the affairs of the state and society. Inscriptions found on clay tablets, metal

plates, and stone walls attest to their charities and other deeds. This is especially true in southern India, where some guilds ran villages and maintained military troops.

Banking/moneylending has been an accepted part of Indian life since later Vedic times. The shastra literature directs terms and arrangements for lending. Lenders might be individuals, families, guilds, institutions, or even the state. In India, as elsewhere, substantial business required the use of credit. Annual interest rates swung between 15 and 25 or even 30 percent, depending on the risks and security offered. (The Laws of Manu stated that the higher a man’s caste, the lower should be his borrowing rate.) Regulations were issued for the settlement of disputes or forfeitures arising from loans. Temple and cave inscriptions tell of interest-only en-

dowments as well as outright gifts to religious institutions.

Currency was another firm pillar of the Indian economy, from the punch-holed coins of the Mauryas. The issuance of coinage was an assertion of sovereignty, and chronologies stamped on the coins have been invaluable in fixing regional dates. Gold, silver, and copper were used for coinage (and sometimes cowrie shells for small change), and professional *shroffs* had the delicate job of determining the weight and worth of the coined metals.

The commercial networks led to the bazaars that were often the features and nerve centers of cities and towns. Goods from near and far were presented in this structured yet freewheeling setting. Varied foodstuffs, textiles, utensils, spices, pharmaceuticals, handicrafts, and other wares were on display.

However, India has always been a largely agricultural land, with most people living in villages either through farming or serving the needs of farmers. The agricultural pattern was well established by classical times, and the *rayat* (peasant) with his simple wooden plow, drawn by an ox or two, was a constant of the countryside. In settled times the state would try to assist by construction of roads, dams, and irrigation channels and perhaps with relief supplies in times of natural disaster. The peasant might own cattle, oxen, goats, or chickens.

Most farmland was held and worked by families, though some was worked by sharecropping tenants and some by laborers. Sometimes a monarchy operated large plantations, and sometimes religious institutions (i.e., temples, monasteries, or universities) might hold substantial estates. Grazing, fishing, or forest foraging rights might be held quite apart from cultivation rights.

Theoretically, all land belonged to the king as "lord of the world." However, the occupancy rights of the peasant were generally recognized by his neighbors, and any land dispute would be adjudicated. The ruler who unjustly seized lands and expelled their occupants might find his rule facing mounting resistance as reports spread. It was usually wiser to keep the peasant producing and instead take the recognized raja's share of the harvest, perhaps one-sixth of the yield (though it might rise as high as one-third). This

land revenue, a mix of rent and taxes, was collected by royal officials, sometimes after hard bargaining between the collector and village leaders. It was the principal source of state income in India until Indian independence in 1947.

Internal trade usually depended on established relationships for the shipping, financing, and marketing of goods at a distance. Businessmen seemed indifferent to the outcome of warfare and political upsets, but they needed security of property and a state that could ensure it. Thievery was a frequent menace in unsettled areas, and wild animals, bandits, or strange diseases might lurk. Merchants often banded together to outfit a caravan, usually of ox carts but in some regions camels or elephants. Professionals would organize such a caravan, with the requisite armed guards. Where conditions were too rugged for wheeled carts, they would resort to backpacks.

Intercity roadways were maintained only when a settled political order permitted. Shipping by sea was easier if one avoided the summer monsoons and occasional winter storms. Principal ports in classical times were Tamralipti in Bengal, Mammalipuram (or Mahabalipuram) in the Southeast, Bharukuccha in the Northwest (Gujarat), and Cranganore in the Southwest (Kerala). But to reach the interior of India, the only reliable rivers were the Ganges and its tributaries, gentle and deep, and the Indus and its tributaries, at times swift and dangerous.

Indian products have been highly valued and much sought in the West since the days of the ancient Greeks and Romans. Most sought have been cottons and pepper. Cotton cloth, made coarsely and massively or in fine and ornate specialized weaves such as calico and muslin, with a variety of attractive patterns and regional specialties, was India's principal export to the Mediterranean, East Africa, and other parts of Asia during the centuries.

Black pepper was even more famous, with the best quality coming from the Malabar Coast (Kerala), spicing up the diets of more and more of the world with the passing centuries. Other more specialized spices were gradually becoming known and appreciated: cardamom, ginger, cinnamon, turmeric, cloves, and, costliest of all, saffron. India was also an abundant source of gems, pearls, and semiprecious stones, often gorgeously

set. Forest products and timber (notably sandalwood, teak, and ebony), aromatics, and handicrafts in ivory, metals, and wood were also exported.

What did foreign merchants exchange for these goods? India's biggest import by far was gold from the Middle East and the Mediterranean world. More surprising was the constant flow of horses from central Asia and Arabian lands; horses always languished in India, perhaps because of the climate or some unknown endemic disease. Slaves were a significant import from East Africa. So were medicinal and aromatic herbs and other forest products, such as frankincense from Arabia, Chinese silks, and woolen and linen fabrics.

In ancient times Indian merchants sailed the Arabian Sea and the Indian Ocean, as classical writings testify. By the fourth century CE Indian merchants dominated the trade to the east, bearing Buddhist monks and doctrines to Southeast Asia along with their merchandise. But in the seventh century Chinese reunification under the Sui and Tang dynasties encouraged the outreach of Chinese merchants into Southeast Asia and eventually India. To the west, Arab and Persian merchants were expanding their scope. The Islamic conquests and conversions seemed to give them extra encouragement and esprit, especially when the caliphate was moved to eastward-

looking Baghdad in 750 CE. By the ninth century the Indian Ocean had become a Muslim lake.

Why had Indian merchants yielded this lucrative carrying trade? Evidently, foreign invasions and political disorder from about 500 CE led to the dissolution of the Buddhist establishment, with its elaborate but costly pagodas, monasteries, and universities, and the revival of exclusivist nativist Hinduism. Buddhism is a missionary religion whose adherents wish to roll the wheel of law through the entire world; Hinduism sees in the foreigner a danger of pollution and corruption. It was reputed that for a high-caste Hindu to cross the *kala pani* (black waters) was to risk pollution and ostracism, even with purification rituals. An exception was the South Indian trade with Southeast Asia. As a result, Hindu merchants gradually lost their stake in oceanic commerce.

■ Introduction: Early Medieval Commerce

While agriculture was by far the largest economic sector during the early medieval age, commerce was a distant second. Two varieties of commerce—local and long-distance—were pivotal during this period. The early medieval world consisted of a vast number of economic regions, local territories that were, as near as possible, self-sufficient in producing most of what they consumed. The demands of city populations for food and other necessities stimulated trade in those commodities with farm folk in the surrounding areas within

their economic region. Most of these economic regions produced all necessities except salt, metals, and sometimes timber.

Regions with sources of these sought-after commodities were pivotal to long-distance trade. Such regions included the seacoast, as well as salt deposits at places such as Salzburg (Austria), Taudenni (central Sahara Desert), or the brine wells of Sichuan (China). Copper mines in Sweden and Michigan, silver mines in sites from Germany's Harz Mountains, central Asia, Japan, or the Andes, and obsidian deposits in central

Mexico and the Yellowstone country also were commercial foci for large areas.

But there was also local and regional trade in other commodities. Pastoral peoples on the grasslands traded horses, wool, hides, and dried meat with agricultural peoples for grain, other foods, and the luxuries produced by sedentary populations. The dwellers of the North Eurasian forests traded honey, beeswax, furs, and forest products for foods and luxuries.

The early medieval trading systems that have been the object for most study involved the long-distance and intercontinental trade routes. These were mainly in the Eastern Hemisphere, but the Americas also had some lesser-known trade systems. The overland Silk Roads or silk routes from China to the Mediterranean and their maritime counterpart, the sea route from Egypt to India and then from India around the Malay Peninsula to China, were the longest and most famous of these routes.

The Chinese exported raw silk, silk cloth, porcelain, tea, lacquerware, paper, and Chinese manufactures on these routes. They received in return horses, furs, wool, cotton, pepper, ivory, rhinoceros horn, tortoise shell, hides, precious woods, cobalt ore, and other raw materials as well as jewels, silver, and gold. India also traded finished manufactured goods, such as steel swords, cotton cloth, gems, silk, religious texts, pepper, and spices, for horses, gold, ivory, and coral along these routes.

Although these two transhemispheric trading routes were the central feature of the early medieval Afro-Eurasian trading system, they were complemented by other trading systems:

- a) The Mediterranean system, in which the Islamic world traded Arab silver and manufactures along with luxuries such as silk, pepper, and spices that the Arabs obtained from India and China for European timber and slaves;
- b) The trans-Saharan system, in which Berber merchants, driving camels across the great desert exchanged manufactured goods from the Mediterranean region and salt from the central Sahara for gold, slaves, kola nuts, and other tropical products from the peoples of the West African savannas and forests;

- c) The East African extension of Indian Ocean trade in which Arab, Persian, Indian, and African sea merchants traded goods from India and the Muslim world for ivory, slaves, pig iron, and (toward the end of this period) gold with the Swahili merchants at the city-states on Africa's east coast.
- d) The Baltic Sea to Black Sea route pioneered by the Vikings in which they traded furs, honey, beeswax, forest products, and slaves with the Byzantine empire and the Muslim caliphates to the south.

The principal trading systems in the Americas were:

- a) The Mississippian trading system, in which the Mound Builders of the Hopewell and Mississippian cultures imported obsidian from the Yellowstone region, pipestone from Minnesota, copper from Michigan, and seashells from the Gulf of Mexico to manufacture artifacts, which presumably were themselves traded. It is thought that the Mound Builders paid for these items with food, particularly maize.
- b) The Mesoamerican trading pattern, in which turquoise from New Mexico was traded as far south as the Mayan cities, and obsidian tools and weapons made in Teotihuacan were widely traded throughout the region.
- c) The Andean trading pattern, whereby Spondylus shells from the Ecuadorian coast were widely traded throughout the Andean region, and fish and other foodstuffs were brought from the lowlands to the highlands.

It is probable that there also existed trading systems and patterns along the Amazon and other great rivers.

India, China, and Buddhism in International Trade

Buddhism was the major influence in the expansion of trade and other contacts between India and China in the first millennium CE. Prior to the fall of the Han dynasty, the religion had entered China with traders from India and central Asia accompanied by some missionary activity of central Asian monks but remained largely limited to those foreigners. During the post-Han dynasty warfare and political chaos, Buddhism gained followers and influence and started to become an important religion in China.

In the fourth century the famous translator of Buddhist texts, Kumarajiva, came to China from Kucha at the invitation of the Chinese monk Daoan, and their disciples subsequently dispersed widely. The spread of Buddhism and the creation of Buddhist temples, stupas, and statues greatly increased under the Northern dynasties. Those formerly nomadic foreign rulers found more affinity with Buddhism than with the Confucianism and Daoism of the previous ethnic Chinese dynasties. They became the religion's adherents and patrons, giving Buddhist teachers from India significant influence in China. This led to greater commercial and diplomatic exchanges between the kingdoms.

Commerce and travel most often took place via the central Asian route that went from India to the Gandharan region, following the Silk Roads through Bactria and Sogdiana, across the Pamirs, around the Taklamakan Desert, and into China. Alternatively, there were more direct but much more rugged trails crossing the Karakorum Mountains, and a sea route also connected China and India. In the fifth century the Chinese monk Fa-Xian traveled to India over the Karakorum Range and then returned to China by sea, his written account being a primary source of information on the Buddhist lands of that time. The sea passage was via the Spice Route down the Arabian Sea coast of India to Sri Lanka and then across the Bay of Bengal. It then went on to Srivijaya, a rich trading center on the island of Sumatra, that commanded the Molucca and Sunda straits. Srivijaya was a center of Vajrayana Buddhism, with religious and diplomatic ties to both India and China, and thus was often a stop-

ping place for monks from both countries. From there ships sailed to Indo-China and then Guangzhou (Canton), with some continuing farther north along the Chinese coast.

The Mahayana school of Buddhism, the most important in China, viewed precious metals, gemstones, and silk as symbols of Buddhist purity and sacred devotion. The Mahayana text known as the Lotus Sutra stated that the Buddha instructed his followers to build 84,000 stupas and lavishly decorate them with the seven treasures. These precious commodities flowed into China: gold and silver from India, central and Southeast Asia, and the Middle East; lapis lazuli (also used to produce ultramarine pigment for Buddhist paintings) from the Kokcha Valley of the Hindu Kush; rock crystal (quartz) from Samarkand; coral from the Mediterranean and Red Seas and the Persian Gulf; red pearls from the Kashgar region; and diamonds and other gems (such as rubies, carnelian agates, emeralds, and common pearls, sometimes alternatively listed as among the seven treasures) from India. Glass, valued for its own decorative qualities, was also often substituted by the Chinese Buddhists for lapis lazuli or crystal. It was commonly obtained from India and Bactria, but higher-quality glasswork was imported from the Middle East and Europe. These items, purchased by Chinese devotees for donation to monasteries and temples, likely made Buddhist institutions even larger consumers of such luxury goods than the secular elites in China during this period. Meanwhile, India and central Asia imported Chinese silk for Buddhist institutions' use.

Buddhism had entered its iconic period in the first centuries CE, and a large trade in Buddhist images developed during the subsequent centuries. Buddhas and bodhisattvas were carved in stone, sculpted in clay, and cast in bronze, in all sizes, as well as painted on a variety of media. Additionally, Buddhist symbols such as lotuses, endless knots, swastikas, and lions were incorporated into utilitarian items such as carpets and furniture. This artwork was in demand among devotees in all the areas of Buddhist influence. Commerce in such art from central Asia, ritual objects from India, and luxury goods from India, the Middle East, and China along with the more mundane commodities combined to make

THE SILK ROADS—BUDDHISM'S GATEWAY TO CHINA

Buddhism's early entry into China was via the Silk Roads, through the oasis town of Dunhuang. Originally established as a military outpost on the western edge of the Chinese cultural sphere, it became an important Buddhist center starting in the fourth century. One of the early Chinese Buddhist monks, Le Zun (Lo-tsun), had a vision of golden light like 1,000 shining Buddhas when stopped outside Dunhuang while on his way to study in India and began carving caves for Buddhist shrines in the hillsides. This effort was joined by other monks and supported by donations from passing Buddhist traders and pilgrims. Buddhist missionaries from central Asia and India stopped there to learn Chinese before proceeding into China and met with pilgrims and students heading west. It thus became a center of Buddhist learning and a repository for Buddhist manuscripts and books. The latter include the copy of the *Diamond Sutra* found there in the early 1900s, which is the oldest known printed book bearing a date, May 11, 868, CE.

the section of the Silk Roads linking India and China via central Asia the most heavily trafficked in the fifth and sixth centuries.

Despite the rise of Islam, Buddhist idols were still being transported westward to be sold in cities such as Baghdad and Bukhara in the late ninth century, with one account mentioning that Buddha figurines worth 50,000 silver dirhams were sold at a fair held in the latter. The extreme geographic penetration of this Buddha trade is shown by a small eighth- or ninth-century bronze Buddha from northern India found in a Viking Age site in Sweden, assumed to have gotten there via the Silk Roads and trade routes through Russia.

After the reunification of China under the Sui and Tang dynasties in the seventh century, the shared religion continued to foster commercial and diplomatic ties to India. Meanwhile, Buddhist monks, artists, and craftsmen also transmitted scientific and technical knowledge between the countries, an example being their transfer of sugar-processing technology from India to China. However, the relationship soon be-

gan to change as the Chinese developed their own Buddhist schools. At a time when Buddhism in post-Gupta India was without support of a powerful state, the Chinese empress Wu Hou promoted it, not only making China more independent of the religious institutions in India but also ultimately making it into a rival as the main center of the religion.

Starting in the eighth century, political instability and military conflicts in the eastern portions of central Asia began to disrupt the overland India-China trade and diplomatic relations. China lost control of its central Asian territories to Arab forces in 751, followed by a period in which Tibetans, Arabs, Uighurs, and Chinese fought over various portions of the region. In the mid-ninth century the Tang emperor Wu Tsung suppressed religions of foreign origin, including Buddhism. The situation started to improve in the tenth century after the Tang dynasty ended, as central Asian trade began to revive. By then, however, the Buddhist connections had become less important, and merchant guilds in both India and China began to assume

the most influential role in commerce between the kingdoms. The increasing shift of trade to the sea routes, where merchants of other faiths were becoming more numerous, further reduced the importance of Buddhism in the commercial relations of the two countries during the Song dynasty period.

Indian Ocean Trade and the Swahili Coast

The Swahili coast of East Africa stretches some 2,000 miles from Mogadishu to Maputo. In this early period our knowledge of the city-states on this littoral is scanty at best. Apart from a few brief and obscure Greek gazetteers, we are reliant on linguistic work and, much more important, archaeological excavations. Important work has been done by scholars digging up the past,

but there are still very many sites along the Swahili coast that have yet to be excavated and analyzed. Studies of these early city-states have also been bedeviled by biased work. Earlier studies often saw the Swahili coast as passively accepting influences, even civilization, from external forces, notably from Shiraz in Persia (Iran) and from the Arab world to the north. More recent work has tended to stress the autonomy of the local inhabitants on the coast. They are seen as playing an active role in accepting and modifying external influences while remaining part of the Bantu-speaking world from which they derived.

There is no doubt that the arrival of Islam on the coast, which happened primarily in the eighth century CE, marked a decisive change. However, long before this the coast had been tied in to the wider Indian Ocean world trading network. By 300 CE Indian and Arab traders had for some centuries been active on the coast, especially in the north in Ethiopia and Somalia. The Greek guidebook *Periplus of the Erythraean Sea*, from the middle of the first century CE, shows us that there was trade as far south as Zanzibar and the mainland coast to the west. A little after this, finds of pottery show contacts with Sassanian Persia and China. At this time, around 500 CE, only the small coastal towns and their immediate interiors were exploited; penetration farther inland came much later.

Arabs had traded to the coast for perhaps eight centuries before the arrival of Islam in the early seventh century. Now Muslims, the Arabs continued their trade. The first mosques on the

► TRADE FROM SWAHILI COAST—IVORY

Ivory, along with gold, was the most valuable export item from East Africa. It is derived from the tusks of male elephants. African elephants produced ivory that was much easier to carve and was more attractively patterned than was ivory from Indian or Sri Lankan elephants. Ivory was much in demand in India, where it was used to make bangles. The demand was constant, for Hindu women break their bangles when their husbands die, and thus new ones are needed.

In the producing areas, inland from the Swahili coast, ivory was not valued. Local herdsmen used

tusks as fence posts and valued the protein from an elephant's carcass much more than the tusks. The huge tusks, weighing at least 44 pounds (20 kilograms) and some even 88 pounds (40 kilograms), were carried to the coast and there exchanged for cloth from India. The Swahili merchants in their port cities facilitated and profited from this exchange. In India the raw tusks were carved by expert craftspeople into fine bangles and other decorative items.

—Michael Pearson

coast date from the eighth century. These were small structures and were used by visiting Muslim merchants and possibly by some Muslim migrants who had settled on the coast. Over the next centuries many Swahili, especially in the north, converted, but it was only from the tenth century that nearly all of the Swahili became Muslims.

The connection of the coast with the Indian Ocean Muslim trading world led to an expansion of trade. Three main items were collected in the interior of East Africa, sent to the Swahili city-states, and exchanged there for manufactured goods from the Muslim world and India. Ivory, which came from far inland, was in demand especially in India for use in making jewelry and ornaments. Gold came from the far south, from the interior area now known as Zimbabwe. Exports began in the tenth century or perhaps a little earlier and were at their height between the eleventh and fifteenth centuries. Slaves were the third main export. They were much in demand in the wealthy Abbasid empire, which flourished from the eighth century in what is now Iraq. These slaves came from the northern part of the coast and were used in backbreaking work draining the marshes of the Tigris-Euphrates delta.

The history of the city-states that funneled this trade into the Indian Ocean world during much of this period is obscure. Archaeologists have excavated a series of small settlements on either side of the Zanzibar channel and also in the Lamu archipelago that date from the sixth to the tenth centuries. The most important change was the transformation of these small settlement clusters into much more sophisticated urban and mercantile societies. This happened between 750 and 950, and it is clear that the arrival of Islam and its opening up of wider horizons were crucial in this momentous transition.

The most important of these new city-states were probably, going from north to south, Mogadishu, Shanga and Manda in the Lamu area, Mombasa, Pemba, Zanzibar, and Kilwa. We cannot provide a list of rulers for any of them, but what we do know is that many of these petty sultans claimed to be originally from Shiraz, in Persia. These claims, which appear to have very little historical veracity, were made in order to give these local dynasties more prestige and to tie them in more closely to the wider Muslim

➤ SINBAD THE SAILOR

Sinbad the Sailor is the subject of a series of travel stories centering around the Indian Ocean trade routes. Sinbad may have lived around 1000 CE in the great city of Baghdad (at that time the capital of the mighty Abbasid empire and a place of great trade), but the tales of the seven voyages of Sinbad do not describe the actual adventures of a real person. Rather, they make up an amalgam of the experiences of many seafarers, with many exciting mythological occurrences added to provide interest. Each story begins with Sinbad living peacefully in Baghdad. He is then seized with a desire to go to sea again. On his travels he has many dramatic adventures. In one he lands on an island that turns out to be a huge fish. In another he escapes by tying himself to a huge bird and flying away. There are also demons and the evil figure of the Old Man of the Sea who traps unwary mariners. The stories are an important part of Muslim literature and have also been popular in Western travel accounts.

—Michael Pearson

world. However, it is possible that some of these dynasties were founded by migrants from Arabia or even Persia, but as they intermarried with local women they became more and more African rather than foreign.

Mediterranean and European Trade

In the centuries after the fall of the western Roman empire, traders in Europe and the Mediterranean no longer had one large geographic area with consistent regulations and taxation in which they could operate relatively securely. The decline of populations and urban centers

Slavic-influenced silver-mounted-crystal pendant found in Gotland, Sweden, tenth–eleventh century CE. Gotland was an important starting point in the river route from the Baltic Sea to the Black Sea. (Werner Forman/Art Resource, NY)

dispersed customers, and the absence of a unified monetary or coinage system, along with a shortage of those coins that were being minted and circulated, complicated trade. Yet extensive commerce continued. The desire for and reliance on continued supplies of imported goods caused most local rulers to grant safe passage to traders and keep duties and tariffs within reason. Greater dangers from piracy and robbers increased the risks, but there were always traders willing to take them in return for the profits that could be made. New towns grew around the medieval markets and fairs. In the absence of sufficient coinage, merchants resorted to barter or used compact commodities as money.

The Mediterranean and Black seas, the Atlantic Ocean, and the North and Baltic seas were the primary arteries of trade in the medieval era. From the seas, rivers then served as the major routes into the center of Europe. The Mediterranean also connected the ports of Europe with the northern ports of Africa, the westernmost ports of Asia, and those of the Black Sea. From the ports

along the coasts and rivers of Europe, carts and wagons were used for commercial transport farther inland where possible, but with few roads being adequately maintained after the fall of Rome, much of the overland transport was by pack animals. Though inefficient for moving large quantities of goods, pack traders carried merchandise anywhere there was a trail passable by horse or mule, thus connecting even remote villages to the international network of commerce.

The items most commonly associated with medieval commerce are the luxury goods transported long distances and purchased by the wealthy: gemstones, silk, furs, dyes, perfumes, spices, hunting dogs and hawks, ivory, ceramics, glass, and objects made of precious metals. The vast majority of medieval international commerce, however, was in commodities and more utilitarian goods traded between areas of abundance and scarcity, purchased by even those of modest means with proceeds from the sale of some of their own produce. Salt was purchased by almost everyone, and even the poorest people required metal tools and utensils for farming and cooking. Grain and other easily transportable bulk foodstuffs, olive oil, honey, wine, wax, wool, flax, and hides were widely traded. Among the most important commodities were the base metals. Iron, being widely mined and smelted, was generally traded relatively short distances. Due to there being far fewer sources of copper, tin, and lead, those metals were transported longer distances, often via the same routes as in classical times. Although horses and other livestock were generally raised and traded locally, there was international commerce in especially desirable breeds and exceptional individual animals. With slave labor being important to most medieval economies, there were numerous local markets for slaves as well as major international trade in slaves.

The extent of commerce is illustrated by some of the communities on the Atlantic islands. In the ninth and tenth centuries they exported to the European continent raw wool, wool cloth, sheep and cattle hides, sour (preserved) butter, lava quern stones, dried fish, furs, down from seabirds, whale bone, walrus ivory, marine mammal hides and rope made from them, and marine mammal fats rendered into oil for lamps

and tar for shipbuilding. They would then import raw commodities such as lumber, iron, and bronze; foodstuffs including grain, dried fruit, ale, and wine; and manufactured goods such as linen cloth, tools, weapons, hone stones, household utensils, pottery, and personal items such as jewelry and mirrors.

Manufactured items of exceptional quality, such as swords and glassware from the Rhine Valley, became world renown and were traded all across Europe, around the Mediterranean, and far beyond. There was also commerce in some surprisingly sophisticated items. For example, rock crystal lenses dating from the tenth century have been found on the Swedish island of Gotland. The lenses, which are believed to have been made in eastern Europe, were intentionally shaped to correct for spherical aberration, thus providing distortion-free magnification, a technique that was subsequently lost for more than 500 years.

Celtic ships and traders had long conducted extensive commerce between the continent and the Celtic-populated islands. Their commercial activities were significantly curtailed when the Visigoths invaded Iberia and the Angles and Saxons, and later the Danes, took control of much of Britain and were further hindered as the Scandinavians gained power in the northern seas. The Byzantine (East Roman) empire continued to dominate commerce in the Mediterranean from Constantinople. However, after Roman control of virtually all the coastal areas from North Africa to Italy had been briefly reasserted, the eastern and southern shores of the Mediterranean were lost to the Muslim caliphate in the seventh century. This included Alexandria and Carthage, which were the trading centers for Africa, and the Levant's ports such as Antioch and Tyre connecting to the Silk Roads and Asia. Although not totally ending trade with these areas, it caused Byzantium to direct more of its maritime commercial activities to the west and north. In particular, new sources of grain were sought around the Black Sea to replace supplies formerly obtained from North Africa. When the Muslims took control of Gibraltar in the eighth century, the sailing route from the North and Baltic seas and the Atlantic islands and coast to the Mediterranean was disrupted. Consequently, separate northern and

➤ INNOVATIONS IN VESSELS OF MEDIEVAL COMMERCE

Two nautical developments led to greater efficiency in sea transport and facilitated the expansion of medieval trade. In the Mediterranean a small version of the lateen sail had been used on coastal vessels since the early Roman period. In the medieval era, however, the Arabs were the first to adapt it to larger ships. By the ninth century it was in wide use on the naval and merchant ships of the Byzantine empire, with the shape refined. Its advantage was that it allowed ships to sail more directly into the wind, making for shorter, faster voyages. A disadvantage, though, was that the very long yard and large sail of a lateen rig required a larger crew and made it dangerous to use in regions where the waters were frequently rough and stormy. Thus, it was not suitable as the primary sail configuration for the northern seas, where the simple single square sail prevailed. Meanwhile, the Scandinavians made advances in the design and construction of clinker-built (lapstrake) ships. They were thus able to construct light and relatively fast yet strong and stable cargo vessels known as *knarrs*. Of the same basic design and having some of the same handling characteristics as the famous longships, they were broader and deeper, enabling them to carry heavy cargoes and cross the open seas. Their easy maneuverability and simplicity of operation also allowed them to be sailed with small crews. These very different innovations in the separate spheres of trade each contributed to greater volume of commerce and lower relative transport costs while creating two distinct styles of ships and seafaring.

—Leonard Leshuk

Mediterranean European trading spheres developed. The Umayyad caliphate in al-Andalus, the Fatimid caliphate in Tunis, and the Abbasid caliphate in the Middle East, although political rivals, comprised a Muslim trading area with a level of commerce comparable to that of Europe. It connected, even if usually indirectly, to the European Mediterranean markets and linked them to the trade routes going into Africa and Asia.

The conflict between Islam and Christianity led to Radhanite Jews serving as the early intermediaries in trade between the two societies.

Long active in international commerce, their role as the main link to the Muslim markets of Spain and North Africa, and also to those of the Middle East, enabled them to gain control of much of western Europe's trade. Beginning in the late eighth century, the Vikings became the pre-eminent traders in the North Sea and the Baltic. In the ninth century they expanded the existing trade routes down the eastern rivers of Europe connecting to Byzantium, with Kiev and Novgorod soon becoming major trade centers. In the south, Italian merchants from Venice, Genoa, and Naples initially operated under Byzantine control. They began to develop into economic and military powers in their own right and assumed a major role in sea trade in the Mediterranean between Byzantium, western Europe, and the Muslim caliphates.

The Radhanite Merchants

The Radhanites (in Arabic, *ar-Radhaniyya*) were Jewish merchant-adventurers who were active during 500–1000 CE. The meaning of their name is uncertain. Some historians believe that it derives from the Persian phrase *Rab Daan*, or “he who knows the way”; others maintain that the name refers to the Rhone River valley in France (called Rhodanus in Latin) that was the origin point for most of their routes. Moshe Gil identified the Radhanites with the district of Radhan in southern Mesopotamia, which he asserted was their base of operations.

Jewish merchants were instrumental in maintaining the Mediterranean and Levantine trade routes following the collapse of the Roman empire and the rise of the Islamic caliphate. During much of this period, Christian vessels were often barred from Muslim ports (and vice versa). Jewish-owned ships, on the other hand, were seen as neutral parties and thus permitted to trade where they pleased.

The name “Radhanite” is known from only a few Arabic sources, the earliest of which is *al-Qitab al Masalik wal- Mamalik* (*The Book of Roads and Kingdoms*) by Abu'l Qasim Ubaid'Allah ibn Khordadbeh. As Abbasid Caliph al-Mutammid's (r. 869–885 CE) director of posts and police for the province of Djibal, ibn Khordadbeh was a postmaster, a sheriff, and a spy; he was therefore perfectly placed to learn about the people who passed through his jurisdiction.

The picture we get of the Radhanites from ibn Khordadbeh is of extremely talented and sophisticated travelers. “These merchants speak Persian, Roman (Greek), Arabic, the language of the Franks, Spanish, and Slav,” he wrote. “They journey from west to east, from east to west, partly on land, partly by sea.” Ibn Khordadbeh described four primary trade routes traveled by the Radhanites; all four began in southern France. Several centuries before Marco Polo, all four routes ended in China (a journey of many months or even years). Ibn Khordadbeh lists the commodities carried by the Radhanites as including spices, perfumes, jewels, silk, and other luxury items as well as steel weapons. The Radhanites also participated in the lucrative slave trade.

The Radhanites and other Jewish traders were highly successful and influential. Jewish merchants received various privileges in the Carolingian empire and were probably a factor in the Khazars' conversion to Judaism. They were probably pioneers in the field of banking; medieval Jewish travelers used letters of credit to transport large quantities of money without fear of theft. Some scholars have credited Jewish traders with the introduction of papermaking and Arabic numerals from South and East Asia into Europe. The Radhanites may also have founded Jewish colonies along their trade routes.

► THE ROUTES OF THE RADHANITES

The Radhanites used four primary routes in their network. The first went from the Rhone Valley, then went south to the Mediterranean, and then went by ship from Narbonne or Arles to Farama (Pelusium) in Egypt. From there the cargo was transported overland to Kolzum (present-day Suez) and loaded on ships for shipment via the Red Sea and the Indian Ocean, stopping in Sindh (now Pakistan) and possibly the Malabar coast before proceeding around the southern tip of Malaya to China (possibly the Yellow River port of Kai-feng, one of the capitals of the Tang dynasty). The second went overland across Syria to Basra in southern Iraq. From there the Radhanites sailed

east through the Persian Gulf before linking up with the first route in India. The third route went through southern France and Spain and across the Strait of Gibraltar into Africa. From Tangiers the merchants proceeded east to Cairo, Baghdad, and the Silk Roads. The fourth route went overland across central and eastern Europe to the Khazar Khaganate and eastward across the steppes to China. It is unlikely that any one merchant routinely traveled as far as China; most likely the cargo was handed from one Radhanite to another as they went back and forth along fixed legs of the journey.

—Brian Gottesman

In the tenth century a number of factors led to the downfall of the Radhanite trade network. The Tang dynasty of China collapsed in 908. In the succeeding decades the Abbasid caliphate disintegrated into a myriad of feuding Muslim principalities, the Khazar khaganate was destroyed by the rising Kievan Rus, and numerous wars broke out on the steppe between competing Kipchak, Kyrgyz, Kimak, and Pecheneg tribes. In Europe the empire forged by the Franks fragmented into smaller states, and the Italian city-states began to take an active part in Mediterranean trade, preying on unwanted competitors such as the Radhanites. The end of the Radhanite age saw a rise in the prices of many Eastern goods in Europe (and vice versa); indeed, many spices that had been readily available in the West disappeared from European tables for half a millennium. For the Jews of both Europe and the Middle East a golden age had ended, and a time of persecution and fear was ushered in.

Trans-Saharan Trade

The Sahara Desert, a vast sea of sand and desolation over 1,000 miles wide in most places, separates the cultures and peoples of Mediterranean lands to the north and the peoples of the grasslands and forests to the south. For much of history, Africa south of the Sahara and the area of North Africa and Eurasia developed as two separate culture areas, each little influenced by the other. But in the third century when the North African Berbers began to use the dromedary camel, the walls of separation were breached to some extent. Trans-Saharan commerce commenced, and people, goods, cultures, and religions made the journey in both directions. To cross the Sahara is a daunting task even today. The slightest miscalculation can result in death by exposure and thirst. In earlier eras it is almost miraculous that people could make the journey. The name "Sahara" is reputed to be the plural of the local word for "desert." One of the major prerequisites of the trade was the existence of powerful and stable states at either end, North Africa and the Sudan. The types of goods that can be carried on the journey have specific requirements as well. They must be relatively easy to transport and very valuable. Both gold and salt fit this category. The other type of commodity that can be traded across the great distances is a commodity that transports itself,

THE MEANING OF THE SILENT TRADE

The earliest descriptions of the gold and salt trade conducted by Wagadu indicated that it was a silent trade. In this scenario the traders from Wagadu would approach the site of the trade and leave salt and other trade goods. They would then withdraw. The miners would then come out of hiding and leave an amount of gold and withdraw. If the traders from Wagadu were satisfied with the amount of gold, they would take the gold and leave their goods. If they were not satisfied, they would simply withdraw. The miners would return and put more gold next to the trade goods. This process would continue until both sides were in agreement, at which point they would take the traded goods and leave.

It is difficult to suggest how communication worked in this context. Some have said that silent trade would have been useful if people did not have a common language to communicate with each other; however, it is more likely that it indicates something else.

The story showed that the traders from Wagadu did not control the source of the gold; in fact, they did not even know where the source was. It was a warning to their Muslim counterparts back at the capital. If outsiders were to attempt to replace the agents of the Ghana and deal directly, they would fail because they would not know where to look. The story foreshadowed what happened when the sultan of Morocco attempted to seize the source of the gold from the Songhay in 1591 and lost all access to the gold for his trouble.

—Douglas E. Saxon

that is, slaves. Finally, a means of transport is required. During earlier eras there was evidence in rock drawings that horses and chariots had made the trip during the last millennium BCE. Linguistic data indicate that this trade was how the horse was introduced to the western Sudan. However, the real birth of the trade needed the arrival of the camel from Arabia in the third century CE.

In the western Sudan south of the desert the state of Wagadu formed in about the third or fourth century CE. This provided the necessary southern anchor for the trade; however, real trade did not begin until the expansion of Islam

in North Africa provided the balancing northern anchor. The main product shipped north was gold from Bambuk and Bure, two areas near the headwaters of the Senegal and Niger rivers. Wagadu, more commonly known as the empire of the Ghana, did not control these areas, but the Soninke rulers of Wagadu did control the trade with those areas. The gold was carried north to Wagadu by donkey and reloaded on camels for the trip across the desert. The northern product of the trade was salt mined in the desert and shipped south from Taghaza. The Sanhaja Berbers were the most important merchants on the northern end of the gold and salt trade.

Wagadu faced a dilemma in dealing with the Muslim merchants. On the one hand the merchants provided wealth through the taxes they paid and commerce through the goods they brought. However, their religion challenged the traditional religious beliefs of the people. Evidence indicates that the Soninke were matrilineal before exposure to Islam; however, Islam is strongly patrilineal. In addition, frequently in African societies women were responsible for engaging in trade in local markets. This view conflicted with Muslim views that women should remain confined to the home. One expression of this conflict was the fact that the capital city of Wagadu, Koumbi-Saleh, was actually two cities connected by a road six miles long. One city was the Soninke city where the Ghana and his court resided. The other city was where the Muslim merchants lived. From Wagadu there were two routes across the desert. The western road terminated in Sijilmasa in modern Morocco. Another route passed to the northeast via the Hoggar to Tunisia.

In the eastern area of the western Sudan near Lake Chad the Kanem empire was established in the sixth century CE. Again the development of the trade had to await the establishment of a stable state on the northern end of the route. This anchor was provided by the Khariji state set up in Algeria in the late ninth century CE. These merchants soon learned the language of Kanem and introduced Islam into Kanem. The rulers of Kanem and the people were perhaps more accepting of Islam than the Soninke because very quickly mosques built in the unique style of the

Khariji were found in the kingdom, and no effort was made to separate the Muslim merchants from the bulk of the people. There were cultural strains put on the society; however, in later years one of the advisers to the Mai or king of Kanem was a woman representing divorced women in the empire. The conflict between the traditional role of the women of Kanem in producing and selling items they manufactured during the dry season conflicted with the proper Muslim view of female seclusion. The result was a large number of divorces and the need for the king to have an adviser.

Since there was no gold to trade north from the Chad basin, slaves instead were the major product. As in the west the product that headed south from the Bilma mines was salt and a more particular mineral product called natron. This was a mineral-laden salt transported in slabs that was reputed to have medicinal powers. The slave trade north hit its peak when the Fatimids replaced the Kharijis after 909 CE. They had need for loyal soldiers who could provide a regiment of royal bodyguards. This corps acted as the Praetorian Guard for the Fatimid imams until their defeat and the destruction of the guards by Saladin in the twelfth century. The rest of the slaves were destined to become domestic servants or, for women, slave concubines. While the numbers and mortality rate were nothing like the Atlantic slave trade, thousands made the journey every year, with the numbers approaching 9 million total. Also almost all of the males were castrated so they could be trusted around the harems of their Muslim masters. Also to provide the slaves Kanem had to raid its neighbors to the south each year, disrupting normal trade relations and causing many groups to seek refuge in the mountains of Guera and the swamps of the Salamat.

Shortly after the end of the first millennium CE the trade was disrupted in the west by the jihad of the Almoravids against Wagadu. Whether or not they actually destroyed the kingdom, they prevented the trade from continuing for years and impacted the economy of the state. Wagadu went into a decline, and the trade was not restored until Mali, its successor state, arose in the thirteenth century.

The Overland Silk Routes

The overland trade routes that connected Europe to China have become known as the Silk Roads. This was not a single unchanging roadway but a dynamic network of roads and caravan trails linking trade centers across Asia on which goods had moved since ancient times. The rise of Byzantium, the expanding Chinese empire in the east, and the later development of Islamic empires in the areas between led to increased demand for imported luxury goods and caused the Silk Roads to assume an especially important role in international trade during the first millennium CE.

From the Chinese capital, Chang'an (Xian), the Silk Roads ran south of the Great Wall to Dunhuang. A route north of the Taklamakan Desert went through the Jade Gate Pass to the towns of Hami, Turpan, and Kucha, with a route farther north branching off at Hami to Urumqi, Almaty, and Tashkent and finally rejoining the main routes at Samarkand. A route south of the Taklamakan went through the Yangguan Pass to Loulan, Khotan, and Yarkand. The two routes converged at Kashgar, where a difficult shortcut to India could be taken south over the Karakorum Range. The main route, however, went west from Kashgar across the Pamir Mountains to Samarkand, Pendzhikent, and Bukhara. An alternative route went from Kashgar down the Wakhan Corridor and through Bactria to Balkh and then to Bukhara. Alternate northern routes went from Tashkent and Bukhara across the steppes north of the Caspian Sea, crossing the Volga into eastern Europe. The main route went southwest to Merv, Hamadan, and Baghdad. The central route then went to the Mediterranean port of Antioch from where goods were transported by sea to and from Europe, while northern branches went overland to Constantinople and the Caucasus,

The Silk Roads traversed desolate deserts as well as towering mountain ranges. This section of the route cuts through the Karakorum Range in western China. (Satish Arikkath)

and a southern branch went to Damascus, Tyre, and Alexandria.

This trade network carried an incredible range of goods. Items with high value in relation to their weight and volume, such as gemstones, precious metal objects, silk, ivory, medicines, furs, decorative glass and ceramics, fine weapons, and spices, were most likely to be traded across the entire length of the routes. More utilitarian goods, foodstuffs, animals, and slaves were also transported on these routes but generally only shorter distances. Although the Silk Roads are often thought of in terms of bringing Oriental goods to Europe, the flow of European goods eastward was at least as important. The Chinese impetus to trade silk, the entire production of which could have easily been consumed by the local elites, was a desire to obtain foreign goods. The balance of trade often favored those on the European end of the trade routes, as indicated by surpluses of coins and bullion of Eastern origin appearing in Byzantium and Scandinavia in this period.

Silk and the Silk Roads provide an early example of globalization of trade and manufacturing. By prohibiting the export of silkworms and sericulture technology, the Chinese initially maintained a monopoly on silk production. But starting in classical times, fabric brought via the Silk Roads from China was often unraveled in Persia or Europe, where better weaving tech-

niques turned it into more desirable cloth. Thus China eventually began selling silk yarn for use by Western weavers. Silkworms were smuggled to central Asia around the fourth century CE, and in the sixth century CE Nestorian Christian monks transported silkworm eggs to Byzantium, breaking the Chinese monopoly on silk yarn production. In the mid-700s central Asian Muslims acquired Chinese silk technology and workers and became major silk producers along with China and the Byzantine empire. With international competition in production, supplies increased and prices fell so that after the ninth century silk was widely available across Europe, and Western-made silk cloth was even traded eastward to China.

In some cases merchants would journey major portions, or even the entire length, of the route with specific goods. More often, though, goods passed through several hands. For example, Chinese silk was traded to the Turkic tribes of Ferghana for horses, the silk was then exchanged for manufactured goods from the Middle East via Sogdiana, and the silk was then traded by the Sassanians to Byzantium for products from farther north. Predating the inception of Islam, the early European and Asian traders were Zoroastrians, Manichaeans, Jews, Orthodox and Nestorian Christians, Buddhists, fertility cultists, and polytheists. Where merchants went they were usually followed by teachers of their respective faiths, making the Silk Roads a route by which religions, languages, cultural influences, knowledge, and technology spread in both directions.

The merchants, who formed the most important link on the Silk Roads especially during the fifth through seventh centuries, were the Sogdians, whose major centers were Pendzhikent (abandoned in the early eighth century), Bukhara, and Samarkand. They had direct trade and diplomatic contact with both China and Byzantium, and their language, an eastern branch of the Iranian group, became the lingua franca along the Silk Roads. Originally Zoroastrians and Manichaeans, they later adopted Buddhism. Economically powerful but politically weak, Sogdiana was considered a vassal state by both the Turks and Chinese and in the eighth century was quickly subjugated by the Arabs.

► ENTERTAINERS AND THE SILK ROADS

In addition to more tangible goods, the Silk Roads carried entertainment across vast distances. Exotic animals for amusement and sport, talented performers (both slave and free), and musical instruments were transported along the trade routes. An indication of the range of such entertainment trade is found in a partial list of the imports of Iraq, giving their countries of origin or transshipment, in a mid-ninth-century work, *The Investigation of Commerce*, attributed to the Arab writer known as Al-Jahiz (real name Abu Uthman Amr Ibn Bahr al-Kinani al-Fuqaimi al-Basri). Listed among the imports were tigers, panthers, and elephants from India; peacocks and racing horses from China; ostriches from Arabia; panthers and black hawks from Barbary and the borders of Maghreb; giraffes from Yemen; trotting donkeys from Egypt; dancing girls from Ahwaz; and valuable zithers and zither

players from Merv. Al-Jahiz's mention of zithers is part of a considerable body of historical and archaeological evidence that allows the movement of musical instruments along the Silk Roads to be traced both east and west. For example, it is known that the Arab *oud* reached China no later than the early years of the Tang dynasty, influencing development of the *pipa* and other lutelike instruments. Transported west, it became the medieval European lute. The Persian *rebab* was carried east to India, while the version played with a bow developed into the tenth-century European forerunner of the violin, the *rebec*. The *sheng*, a Chinese reed pipe mouth organ, spread to central Asia and became a common instrument in Buddhist temples, while the central Asian two-stringed lute entered China, where it evolved into the *erhu*.

—Leonard Leshuk

Travel was almost always undertaken as part of a caravan utilizing pack animals: horses, donkeys, mules, camels, and, when crossing the high mountains, sometimes even yaks. Where marauding nomad tribes were a threat, traders would seek safety in large numbers by forming caravans of 1,000 or more travelers with their pack animals. Oases along the routes grew into rich trading towns and cities that owed their prosperity largely to the commerce that passed through them. Their rulers thus generally sought to make travel safe and would often provide military escorts to caravans. Fortified caravansaries were also built at intervals of a day's travel.

Over the centuries, control of central Asia changed hands among numerous tribes and empires, sometimes resulting in temporary disruption of commerce or causing shifts in the preferred routes through the region. Political and social changes in China periodically affected how eagerly the foreign merchants were received there. By the Song dynasty period, merchants from the West usually obtained Chinese goods from central Asian tribes rather than penetrating China itself. Meanwhile, advances in shipbuilding and safer ocean passage to China allowed more economical transport of goods be-

tween Europe and the Far East by sea. Thus the importance of the Silk Roads in linking East and West had already begun to decline by the eleventh century. Portions of the overland routes remained the primary channels for commerce within central Asia. Transport via deserts and cool mountains also continued to be preferred by some traders for the land route's most famous commodity, silk, that was easily ruined by mold in the damp holds of ships traveling for months through hot, humid climates and tropical storms.

Trade Diasporas on the Malabar Coast in the Age of Sinbad the Sailor, circa 800–1000 CE

The tales of Sinbad the Sailor incorporate the reality of increased Middle East contact with the Indian Ocean during the ninth century, consequent to the expansion of the Maritime Silk Roads to China after the establishment of the Abbasid caliphate capital at Baghdad in 762. The fictional Sinbad tales were based on popular word-of-mouth and written portrayals of the Indian Ocean realm in a series of Arabic-language geographical texts that provided “firsthand” accounts of their author’s Indian Ocean travels but were often collections of “fact” supplied by others who had made Indian Ocean voyages.

Collectively, these Middle East sources focus on India’s southwestern Malabar coastline, which was the destination of voyages based out of the Persian Gulf or the Red Sea. There, most Middle Eastern merchants were content to trade for the products that arrived on ships from the East, while some Middle Eastern merchants made the onward passage to China. Middle East ships brought with them copper, African ivory, incense, turtle shells, glassware, and horses, which were exchanged for gold, pearls, silk, cotton, ceramics, a variety of jungle products (e.g., sandalwood and rhinoceros horns, which were believed to have medicinal value), and spices (including Malabar pepper). Muslim, Christian, Zoroastrian (Parsi), and Jewish traders of Middle Eastern origin began to make Malabar ports of trade their home. Contemporary Indian-inscribed stone and copper plate documents provide local accounts of their activities and interactions.

The Stahnu Ravi plates (ca. 850) are the single most important document of the ninth century CE for the study of West Asian trade diasporas in South Asia and consequently for the understanding of southern India’s place in the early international trade of the Indian Ocean. The plates are multilingual: the main text is in Tamil, and the testimonials are in Arabic, Pahlavi, Judaeo-Persian, and an as yet unidentified northern Indian language, representative of the major resident trade diasporas active in the Malabar Coast marketplaces at that time, who

were variously networked with the Persian Gulf, the Arabian Peninsula, and northern India.

The grant texts concern intimately linked issues: the establishment of and terms of management appropriate to a new port of trade and its marketplace; the endowment of a Nestorian Christian church at the port of Kurrakeni-Kollam, near modern-day Quilon (Kollam) in southern Kerala; and the allocation of trade privileges to two trade associations. Among those participants and witnesses of the grant certification rituals were three different Middle Eastern ethnic groups who were using the local marketplace and presumably held community residential stature, whether part-time or permanent. Their validations were written in scripts representative of their places of origin. These networked regional homelands in the Persian Gulf and Arabian Peninsula regions were vital to the Kollam port’s success. Contemporary Middle Eastern anonymous sojourner accounts collected in the *Akhbar al-sin wa al-hind* (ca. 851) assert that Kollam was by then the chief port of call and taxation before entering the wider Indian Ocean. The Malabar coastline was the point of intersection of Arab, Persian, and Chinese shipping, and Kollam was the guard post attached to the country of Koullam-Malaya, which took taxes on China trade ships to the amount of 1,000 dirhams and 10 to 20 dinars on other ships.

The inscriptions distinguished the trading rights of the Anjuvannam (foreign diasporas) and Manigramam (Indian) trade associations and their responsibility for the administration of trade in Kollam. They were exempted from customs duties on incoming and outgoing articles and a tax on bondsmen who served their marketing needs. They had to pay fees on their vehicles for the transport of goods—eight *kasu* (gold coinage) on land vehicles and four on boats—both on their entrance and exit from the marketplace.

Kollam was not an open free trade marketplace but instead was an administered marketplace. This is significant in that administered marketplaces ensured fair exchanges of goods and services in a marketplace where the self-interests of foreign visitors and multiethnic residential communities needed to be checked. To this end, the Anjuvannam and Manigramam

were to be present at the collection of duties to ensure equitability, the assessment of the value of commodities coming into the market, and handle all other market business. They were thus the district governor's agents in the marketplace, assisting in or delegated to make assessments and collections. They were also entitled to administer and collect lease fees from local market stalls. A palace agent collected the local king's due. The *Anjuvannam* and *Manigramam* collected the local king's due. They were delegated as the chiefs within the market area or as the agents of the two local chiefs named as attending the grant certification ritual. They held ultimate income rights over the property that was included within the jurisdiction of the new port-of-trade community.

The grant enumerates the 72 rights of the *Anjuvannam* and *Manigramam*. Among these was the privilege to carry earth and water on the back of an elephant and to ride on elephants during marriage ceremonies or on other auspicious occasions, rights granted to them "for all time"; the right to withhold ceases on merchandise exported beyond the king's realm if any disputes rose between them and other groups until a resolution was reached; and jurisdiction over their own affairs.

The grant's linked focus on a Nestorian church shows the importance of religion to these diasporic merchant groups in their new homelands, as the endowment of the Nestorian Christian church served as a center for specific religious practices. The church, as a building and as a community, provided a source of ascribed or constructed social meaning to those seeking an identity and personal security in a foreign land.

While the *Stahnu Ravi* inscriptions are the most detailed local accounting, other contemporary Malabar coastline inscriptions confirm these characterizations of the Kollam trading diasporas. An early eleventh-century inscription from the port of Cochin similarly details the establishment of the Kodungallur (Cranganore) marketplace under the administration of a residential Jewish community led by the merchant Joseph Rabban. The initial eleventh-century accounts of Jewish diaspora activities in the region

contained in the Cairo Geniza collections report early partnerships among Jewish, Christian, and Muslim communities, which were distinct from the Hindu agrarian settlements that lay adjacent to their commercial centers. The archaeological remains of early mosques and a 788 CE tomb near the port of Calicut document the first Muslim settlements. Subsequent Muslim accounts substantiate the founding of the regional Mappilas ("Big Child") Muslim community in this era, notable for their practice of *muf'a* (temporary marriage), which established a network of port wives to provide local representation in their husbands' periodic absence.

These inscriptions demonstrate that the early western Indian Ocean maritime diasporas were not exclusively commercial in nature but instead overlapped into meaningful societal, religious, and political affiliations. These and the other ninth- through early-eleventh-century evidence of regional networking in the western Indian Ocean region suggest that maritime diaspora were acculturating into local societies or negotiating relationships with their neighboring communities, as these early commercial interactions and the resulting stable pluralistic communities contributed to the Indian Ocean trade boom that followed.

Sogdians on the Silk Roads

The fall of the Kushan empire in the third to fourth centuries CE coincided with the emergence of the Sogdians as the most prominent traders on the Silk Roads, suggesting that they possibly were replacing Indian and Bactrian merchants who had operated under the aegis of the Kushans. That Indian influence may be seen

SOGDIAN HOMELAND AND SILK ROAD ROUTE, 300–1000

in the Indian terms connected with the trade that were used by the Sogdians. The account of Samarkand in a history of the Tang dynasty adds the information that “When a child is born, they give it a piece of rock honey to suck on and place sticky glue on the palms of its hands, desiring that it would have sweet words when grown and would latch on to valuable things as if glued to its hands. . . . They are good at commerce, love profit, and when twenty years old, they go out to other countries, they go wherever there is any profit to be made.” The Byzantine sources tell how the Sogdian merchants, in close cooperation with the Turkish empire on the steppes in the sixth century, took control of the silk trade with Persia and through Persia with the Byzantines. When that plan failed, however, the Turks and the Byzantines formed a close alliance against Persia.

The Sogdians were more successful in their trade to the east although there were setbacks, especially during periods of disorder in China. A number of letters found at a watchtower of the

Great Wall, written in Sogdian and probably dating from the early fourth century, provide vivid evidence of the difficulties faced by those early merchants. But there was a continuing migration of Sogdians into China, and the settlements flourished, especially at capitals such as Luoyang. A contemporary description of Luoyang, the *Luoyang qielanji*, speaks of the large numbers of foreign merchants who have carried the rare goods of the world to that capital. In return for silk and other Chinese products, the Sogdians as traders or as envoys brought saffron, stone honey, medicinal herbs, perfumes, carpets, silver, gold and glass artifacts, rare jewels, ostrich-egg cups, animals such as lions and leopards, and even dwarfs, musicians, and dancers. The Sogdians so dominated the trade from the fourth to the eighth centuries that their language became the lingua franca of the caravan routes.

Although there is much literary evidence that testifies to a large Sogdian population in and around China, there is little archaeological evidence of their presence. Recent discoveries of a

number of burials of the sixth and early seventh centuries now provide a firsthand look at the burial practices of some Sogdian residents in China and a glimpse into their lives, or how they preferred to be seen.

The forms of these burials are unlike anything seen in Sogdia itself but instead represent an adaptation of Chinese practices to Zoroastrian beliefs. Stone coffin beds prevented the human remains from polluting the earth, and there were few if any grave goods, as the Zoroastrian funereal rites prescribed, but the style of the tomb was Chinese, and there does not seem to have been any attempt at de-fleshing the body before it was interred. The decor of the tombs, carved into the walls of the stone vault or on the stone screen placed around three sides of the coffin bed, provide unique depictions of Zoroastrian beliefs, illustrating in some cases what had only been known from literary sources.

A network of Sogdian communities followed the trade routes across central Asia, through the Gansu corridor, and into northern China. The responsibility for administering the Sogdian communities within the Chinese realm was given to the leaders who were given a low rank in the official hierarchy. The Sogdians entered into Chinese society in many ways, as merchants but also as farmers, craftsmen, grooms, and translators and in the military. During periods of unrest and warfare Sogdians took part on all sides. The most famous of these was the mid-eighth-century rebel An Lushan (Sogdian *rwššn*, or “luminous, light”), whose father was Sogdian and mother was Turkish. Having become the commanding general on the northeastern frontier, he led a rebellion (755–763) that almost brought down the Tang dynasty. His eventual defeat and the reaction that followed may have contributed to the quickening pace of assimilation of the Sogdians into Chinese society, for by the ninth century only their surnames reveal their ancestry.

➤ AN ENCOUNTER WITH MEDIEVAL SLAVE TRADERS

One of the most detailed contemporary descriptions of medieval slave traders is that of the Rus observed by the Arab chronicler Ahmad Ibn Fadlan in the land of the White Bulgars along the Volga River. Scholars have raised questions in relation to Fadlan’s “Rus,” who differ in a number of aspects from what archaeological evidence and other historical accounts, such as that by his Persian contemporary Ahmad Ibn Rustah, tell us about the Scandinavian traders of the period. However, the relevant passages in Ibn Fadlan’s *Risala* present some colorful and fascinating images.

Fadlan tells of the Rus bringing slave girls and furs down the Volga, offering sacrifices to wooden idols in anticipation of, and later in thanks for, successful sales. He was appalled by their licentious behavior in public with the female slaves and by their personal hygiene but was favorably impressed by their physical stature and wealth. He depicts them as showing a very callous attitude toward anyone who fell ill, giving minimal provisions and care and even less in the case of slaves. Most sensational is the detailed description of the funeral of a wealthy chieftain in which a female slave volunteers to be cremated with him on a pyre constructed from his ship hauled up on the shore. Artistic license taken with this impressive ritual in works of fiction in recent centuries has led to a widely held image of Viking funerals in which ships were set adrift and then set on fire, even though no historical or archaeological evidence for such floating funeral pyres exists. More recently, Fadlan’s encounter with the Rus has itself served as the inspiration for macabre historical fiction, having been merged with the story of Beowulf in Michael Crichton’s novel *Eaters of the Dead* (1976) and its cinematic adaptation, *The Thirteenth Warrior* (1999).

—Leonard Leshuk

Slave Trade from Northern/ Eastern Europe and Central Asia

Slave labor played a significant role in most medieval economies, making trade in slaves an important part of international commerce. The European slave trade declined near the end of the western Roman empire because fewer slaves were taken in war, estate owners were reluctant

THE REMNANTS OF SLAVERY IN OUR LANGUAGE

Several words relating to slaves and slavery from the medieval period remain in our language. Whereas the term “slave” itself is generally accepted to have derived from the name of the central European Slavs who were among those being taken as slaves, it appears that the opposite happened in the case of the Welsh. Initially applied to all Celtic inhabitants of Britain by the Anglo-Saxon invaders, the origin of “Welsh” is their word *waelh/wealas*, used interchangeably for foreigner or slave and reflecting the attitude that all those of other ethnic groups were considered potential slaves. Evidence that the slave-taking in the struggle for control of Britain in that period was not one-sided is found in a play on words that works as well in English as in the original Latin and was reportedly made by Pope Gregory. Seeing a group of blond blue-eyed youths being sold in the slave market in Rome, he inquired as to their origin. When told that they were Angles from Britain, he replied, in reference to their angelic appearance, “They are not Angles, but angels.” Although not denoting a particular group of people, an Old Norse word for slave or bondservant, *thrall*, survives in English. The verb “enthral,” literally meaning “to enslave,” is now used as a word meaning to fascinate or spellbind. Mamluk (alt. spellings *mameluk/mamluke*), an Arabic word meaning “owned,” was initially applied to soldier slaves such as those used by the Turks. The mamluk armies grew so efficient and powerful that they became a political force in their own right, ceasing to be slaves and evolving into a military caste. Egypt and various areas in the Middle East were at times seized and ruled by these soldiers so that now, in English, the term “Mamluk” is more often associated with ruling dynasties or sultanates rather than with slavery.

—Leonard Leshuk

to invest in slaves when the labor of freemen could be hired cheaply, and it became more difficult to prevent slaves from escaping. However, slavery persisted and evolved in the countries that succeeded the empire. In some countries there were hereditary slave classes. People were also enslaved as punishment for crimes or as the result of debt, with impoverished parents some-

times reduced to selling their children into slavery. Most commonly, though, in Europe as in central Asia slaves were taken from among defeated enemies or in raids.

The possibility of being taken captive as the result of war or in a slave raid was an unpleasant fact of life in medieval Europe and Asia, particularly for those living near seacoasts and borders. Shipborne slave raiders could appear suddenly at a village on a coastline or isolated estuary, attack, and sail away with captives before any resistance or pursuit could be organized. Inland in Europe and across central Asia, well-armed slave raiders on horseback relied on being so formidable and intimidating that the sedentary agrarian populations would be unable or unwilling to put up effective resistance. Their captives, usually bound or at least tied to one another, would then be marched to the distant slave markets. Women and children were more likely to be taken as slaves than men, who were more difficult to catch and subdue and would more often later escape or attack their owners. In central Asia it was common to kill all adult male captives or else cripple them in a way that allowed them to work but made escape difficult.

Slaves were widely used for agricultural and unskilled labor, but such workers were of low value and generally did not get traded long distances. The international slave trade consisted primarily of those who brought higher prices. These included young women to be concubines, sometimes as members of large harems, or to be household servants; boys who could be trained for specialized work, sometimes emasculated into eunuchs to make them more docile and deter escape by making them social outcasts; boys who could be raised as soldiers; and individuals with special artistic, technical, or administrative skills. Slavery, however, was not necessarily a hopeless or permanent fate. Throughout the era, many notable figures were taken as slaves and then later regained their freedom. The boy who grew up to be Ireland’s Saint Patrick was seized on the coast of Britain at the end of the fourth century by Irish raiders, and Olaf Tryggvason, one of the most famous kings of Norway, was taken as a boy by Danish or Baltic raiders in the tenth century and enslaved in Estonia. The former escaped with relative ease when he was a

young adult, and the latter was spotted on the streets of Tallin by a merchant uncle who purchased his freedom.

Christian and Islamic societies officially or tacitly allowed their members to keep slaves of their own religion but generally prohibited, or at least discouraged, trading in them. They also prohibited members of other religions living within their societies from owning or trading in those professing the predominant religion. The peoples of northern and eastern Europe and central Asia who did not yet adhere to the monotheistic religions of Middle Eastern origin fell totally outside these rules and protections. They therefore took slaves from and were subject to being captured and sold as slaves by both Christians and Muslims.

The major slave markets in Europe were in Prague, Kiev, Constantinople, Khorsun, Cologne, Marseilles, and, later, Genoa. The Vikings were active in long-distance international slave trade, with Bristol and Dublin being known as slave markets by the tenth century. They appear to have traded some slaves from these markets to Muslim Spain. However, the extent of Viking slave trade is unclear despite speculation that the sale of slaves may have, at times, produced a major portion of their income. They are known to have often requested only modest ransom payments to release prisoners, indicating that there was no great desire to keep or sell them as slaves. As the Rus gained control in eastern Europe, they took slaves from among the nomadic Slavic and Turkic tribes for sale in Kiev, Constantinople, and Baghdad.

Christian countries in western Europe took slaves in battles against unconverted Saxons, Scandinavians, Magyars, and Slavs. The large number of Slavic prisoners taken in central Europe resulted in the Latin word for Slav, *Sclavus*, being applied to any captives sold into bondage; this is the origin of the English word "slave." Many of these captives were sold to the Muslims occupying Spain. Since Christian and Muslim nations generally would not trade directly, starting in the Carolingian period charters were given to Jewish Radhanite merchants, allowing them to transport non-Christian slaves across Christian territories to Spain. These traders operating from Arles, Marseilles, and Verdun became dom-

inant in the European slave trade. They also took such slaves beyond Byzantium to sell to the Khazars, who then sold them in Baghdad and other Middle Eastern slave markets. Later in this era when trade between Europe and the Muslim caliphates expanded, slaves from northern and eastern Europe were also purchased by Genoese and Venetian merchants, who traded them to Islamic countries around the Mediterranean.

In central Asia, warring nomadic tribes raided and enslaved both their nomadic enemies and sedentary neighbors and sold them to the Islamic societies to the south. Muslims took other Muslims as slaves in their civil wars, often declaring their rivals heretics and infidels and thus not due the protections of religious law. In the early eighth century Qutayba, the governor of Merv, took so many captives in suppressing rebellions and in his other military actions that sales of them temporarily depressed the prices of slaves in the markets of Kufa, Basra, and Merv. Slave trade increased in the eighth century when the Abassid caliphs, like their Umayyad counterparts in Spain, began purchasing many male slaves to use as soldiers. Mainly Turkic youths from north of the Syr Darya, such slaves were first purchased in the markets of Baghdad and later bought from Samanid governors of the Transoxiana area. The Samanids themselves in the tenth century became the first central Asian dynasty to utilize a mainly slave, or *ghulam*, army. With the individual soldiers able to earn progressively greater privileges and responsibility as they proved their loyalty and valor, some rose to positions of political power. Such slave armies would soon determine the course of history in much of the Islamic world.

The Trading System of the Mississippi Mound Builders

The Mississippi Mound Builders culture was very dependent on long-distance trade in prestige goods. The leadership of this cultural group, also known as Mississippian culture, used imported goods to establish their positions among the ordinary people. These goods were also used in religious rituals, especially in burial rites.

Unlike the contemporary Mesoamerican trading system, the Mississippi Mound Builders culture did not use extensive long-distance trading routes to obtain goods. Instead, they relied on a hand-to-hand system in which neighboring people obtained goods from more distant peoples and passed them along. Archaeological evidence proves that the Mound Builders valued goods obtained from long distances. Individuals who apparently had great social importance were buried in mounds along with large quantities of goods. These goods included seashells from the Gulf Coast, copper ornaments and tools from the Great Lakes region, and precious stones from the Southwest. Graves of ordinary people have yielded smaller numbers of goods that originated in the region.

The dominant culture in the region by 300 CE is known as the Hopewell. It originated in southern and central Ohio and influenced peoples living in current-day Indiana, Illinois, and Kentucky. One of the most important aspects of Hopewell culture was the skill with which various kinds of stone were worked. Blades made from local supplies of chalcedony and flint were highly prized by neighboring peoples, as were obsidian blades made from stone imported from the Rocky Mountains. The Hopewell people exchanged their products for items from as far away as upper Michigan and the Gulf Coast. Imports included copper, which was made into ear spools, breastplates, and decorative items, and galena, which could be made into white paint and sparkling powder. Mica from southern Appalachia was separated into sheets and cut into various shapes, such as hands. Shells, alligator teeth, and turtle shells came from the Gulf region.

Goods were not the only things exchanged among the different peoples. Religious concepts

and rituals were also shared and helped to form the region into an exchange network that valued the same sorts of items. The mounds that marked this culture were the centers of religious and political authority. A limited amount of maize was grown among the Hopewell people, and some archaeologists believe that it had a religious significance greater than its role as food. The Hopewell culture began to decline by 400 CE, evidenced by a decline in trade. Fewer imported items can be found in burial sites from this period. One explanation is that the Hopewells' trading partners found new supplies of the goods they wanted, such as copper. Another is that the replacement of the atlatl by the bow and arrow caused an increased amount of warfare among the people of the region, leading to the breakdown of trading relations.

People in the Ohio and Mississippi river valleys had developed sedentary societies before the Common Era based on the domestication of native plants supplemented by hunting. These plants include sunflowers, goosefoot, and erect knot weed. Although they were familiar with maize, the people apparently preferred foods that originated in the region. Maize did not become an important food crop in the Mississippi and Ohio river valleys until around 800 CE, with the rise of another mound-building culture, the Mississippian. The Mississippian people also raised squash and beans developed in Mesoamerica, replacing many of the native foods previously grown. The greatest center of Mississippian culture was Cahokia, near present-day St. Louis. By 900 CE, it was the largest urban center north of Mesoamerica. Unlike the earlier Hopewell culture, the Mississippian culture was dependent upon maize as its chief food crop. Cahokia was the hub of an extensive trade network. Many of the goods, however, came from different regions than those of the Hopewell culture. Flint was imported from Oklahoma, while galena came from Missouri. Southern Appalachia provided copper. Stone hoe heads, buffalo hides, and decorated pottery also were important trade goods. Water routes following the Mississippi north and south as well as the Missouri and Ohio rivers to the east and west all helped make Cahokia an important trading center. The Mississippian culture did not use large canoes to haul large amounts of trade

HOPEWELL TRADING SYSTEM, CIRCA 600

goods, like in Mesoamerica, but relatively small amounts of products could be moved by water. The alternative overland method was limited to how much a man could carry, since wheeled vehicles or pack animals were not available.

The ability of agriculture to supply steady amounts of food caused the population to increase. As a result, the Mississippians developed a more complex social order. A government of hereditary chiefs was established. These chiefs

and other members of their elite class were expected to perform certain duties, such as defending the settlement against outsiders. In return, the ordinary people provided them with food, necessities, and labor. Possession of imported prestige goods helped to confirm the status of elite classes among the Mississippians, helping to promote the trade among people of the region.

Mesoamerican Commerce

During Mesoamerica's classical era, from about 300 to 800 CE, highly developed trade routes and patterns were created. This commerce consisted primarily of long-distance trade in luxury and prestige goods between different states. Many of the trade items also served as tribute from vassal states to their rulers. As a result of the interaction, the Mesoamerican cultures came to share many ideas as well as religious concepts and art.

Mesoamerica did not develop an elaborate road system, such as that of the Andean states. Long-distance trade was also hampered by the lack of beasts of burden and wheeled vehicles. Most goods were carried by professional porters using pack frames and tumplines over various landscapes. Because of their limited carrying capacity (about 50 pounds), most long-distance trade was limited to low-weight high-value luxury or prestige goods. These products were con-

sumed by the local elites in religious or social displays. Bulky food products such as maize were not normally traded except on a local basis.

An alternative to human porters was water transportation. Only a few rivers in Mesoamerica were suitable for this method, limiting the use of water. Large inland lakes and coastal waters, however, were often used to transport bulky and relatively inexpensive goods. Dugout canoes were most often used to carry goods. A single man could move a ton of goods at the same speed as a walking man, making water transport much more efficient. Canoes could reach up to 100 feet long, with a corresponding cargo capacity. Both canoes and rafts were used in the Gulf of Mexico, where they used currents and paddles as their primary means of motion. Sails were unknown in Mesoamerica.

The dominant city-state in the Classical Period Mesoamerica was Teotihuacan. Although much of its power was thanks to military success, Teotihuacan also depended on an extensive commercial network. Settlements of merchants from Teotihuacan were located in many other urban centers of the time, and corridors of Teotihuacan settlements from the city to its trading partners ensured the safe passage of goods.

The most common products involved in Mesoamerican commerce included ceramics, obsidian, textiles, high-quality stone tools, metals, precious stones, and specialized tropical goods. Ceramics were relatively heavy objects, and many were traded from culture to culture in Mesoamerica as packaging for other goods. Elaborately decorated ceramics, however, were considered prestige goods by the elite classes of Mesoamerica. Most of these originated during this time from the Gulf Coast and coastal Guatemala. Their use was reserved for royalty and nobility, who used them in public displays. The artwork on the ceramic dishes and pots influenced the artwork and religious concepts in the communities that imported them, helping to create a more unified culture throughout Mesoamerica.

Another important trade good was obsidian. This volcanic glass was found in only a few places in Mesoamerica, but people throughout the region recognized its importance for making cutting tools. Modern archaeologists can use

Dried cacao beans and pod, used as a medium of exchange in Mesoamerican commerce. (Howard Sandler)

chemical analysis of obsidian tools to work out trade patterns that existed. The obsidian from the Pachuca area of central Mexico was the most widely traded not only because of its technical qualities but also because of its greenish color. Other green and blue stones were used by the elites in displays intended to solidify their status. Turquoise from the regions north of Mesoamerica was traded throughout the area. Rock crystal, mica, and onyx were among the other desirable items. Decorative and religious items made of gold were widely traded from their origins in Oaxaca and Central America. Similar items made of bronze were imported from Mexico during the period as well. All of these goods were prime trading goods thanks to their relative light weight and small mass, making them easier to transport.

Cotton and maguery textiles were widely traded among the Mesoamericans. A standardize-sized cloak became a basic currency among the peoples, since it could be fashioned into useful clothing. Cloth was also relatively light and compact, making it suitable for carriage by human porters over long distances.

High-quality stone tools, made from chert from Belize, were commonly traded in Mesoamerica. These tools, such as metates for grinding maize, were relatively heavy but appeared throughout the region. They were superior to locally produced stone products and were highly desired.

A few food items that were not widely available were traded. Salt was produced in coastal areas and was in wide demand. Cacao beans were also widely traded and eventually were used as a form of currency in most of Mesoamerica.

Miscellaneous trade goods included rubber balls used in the ball game played throughout Mesoamerica. Thousands of masonry ball courts have been identified in Mesoamerica, and the rubber balls that were used had to be imported from tropical lowlands where rubber trees grew. It is estimated that the Aztecs alone imported approximately 16,000 rubber balls to their capital each year, giving an indication of how significant the trade in rubber was.

Metal objects were imported from western Mexico during this period. Craftsmen learned the techniques and secrets of metalworking from

➤ CACAO CURRENCY

The cacao bean assumed the role of money in most Mesoamerican commerce. The beans were small and easily transported. Cacao beans also were valued by all inhabitants of the region, making them a universal currency. Individual and small numbers of cacao beans could be used to make change, giving the cacao bean a flexibility that other products often lacked.

—Timothy J. Watts

merchants from South America and developed a range of goods intended to meet the social needs of elites in Mesoamerica. Bells, tweezers, and rings were made at first from copper, highlighting the status of the user. After 1200 CE, craftsmen developed a range of goods made from bronze alloys. By varying the amount of tin or arsenic in the alloy, they could make the objects look more like silver or gold. Even though silver and gold were readily available, their durability was less than that of bronze.

Andean Trading Patterns

Trade and commerce in the Andean region between 300 and 1000 CE was mostly limited to luxury goods and those items that could not be produced locally. The emphasis among the Andean communities was on self-sufficiency. The geography of the region greatly influenced the pattern of trade.

To support themselves without having to depend on outside resources, the Andean peoples

Quechua Indian uses llamas to transport goods for trade, Peru. Most Andean trade goods were carried on the backs of humans or llamas. Wari and later Andean civilizations constructed an extensive network of roads which facilitated this commerce. (Zbigniew Bzdak/The Image Works)

developed what have been called vertical archipelagoes. Different ecological systems existed within close proximity to one another, depending on the elevation. Different agricultural products were produced at different elevations. Higher elevations were good for supporting llama herds. Lower ones were used for growing vegetable products, such as potatoes. By controlling different ecological areas, a people could grow different crops. In this way they were also more protected against disasters such as poor harvests or pests. Their diet was also more varied as a result.

The earliest state in the Andes during this period was Moche, on Peru's northern coast. The capital of Moche was marked by large public buildings devoted to religious and political purposes. A high degree of craft specialization was also evident at Moche. Archaeological evidence indicates that the elites had access to clothing, jewelry, and other luxury items imported from different regions. Moche was succeeded after 500 CE by two newer states, Tiwanaku and Wari. Both states exerted considerable influence over their neighbors through conquest and religious conversion. They also used a practice of sending colonists to an area that produced desirable goods. The colonists would retain their membership in the larger po-

litical organization but would produce goods that could be traded back to the home state. In turn, they would receive products from the Andean highlands.

All three of these early Andean states practiced self-sufficiency as much as possible. Even so, a thriving long-distance trading network existed. Caravans of llamas were used to carry local products for trade with other peoples. Local products from the Andean states included dried llama meat, potatoes and other tuber products, hides, fats, and textiles. As the caravans passed along their routes, they would have bartered for products not produced in the mountainous regions. Most of these products would have been luxury or status goods, desired for religious or political reasons. These products were desirable because of their unavailability from local sources. Maize, for example, was grown by farmers in the coastal settlements along the few rivers flowing into the Pacific. Andean leaders needed maize to brew a local beer that was used in religious rituals and was also provided to workers as part of their pay. The same settlements also provided red shells from the spiny oyster, used in the production of jewelry. Some food products were bartered from the same settlements. Dried fish were obtained there as well. Salt, a vital product, came from coastal villages. Other trade goods included objects made of gold, silver, and bronze. Obsidian for tools was obtained from a few locations in the Andes.

The total amount of goods traded in the Andean region was relatively low. Because they were primarily luxury and prestige goods, their overall effect on the region's economy remained low. The trade did help to unify states, however, as well as reinforce the status of their elites.

■ Introduction: Cities in Early Medieval Economies

While most economic production in the early medieval world was connected with agriculture and occurred in rural areas, cities played crucial economic roles. Early medieval cities were primarily administrative, religious, and pilgrimage centers; secondarily commercial hubs; and only occasionally manufacturing (handicraft) centers. Most of the cities were small, even miniscule, by modern standards, but a few early medieval giant cities, the capitals of great empires, had populations ranging from 500,000 to almost 1 million. China's capital, Chang'an, is said to have approached 2 million.

The large capital cities had the greatest economic impact. To these capital cities the taxes of great empires, much in the form of grain, flowed, and there it was spent. There great numbers of people were employed in the feeding and care, the entertaining and the pleasure, the disciplining and the punishment, the training and education, and, most importantly, the defense and protection of the ruling families and the swarms of functionaries. This imposed an economic burden on the state that was paid for by the wealth exacted from the rural countryside of the empire.

A great expenditure supported by the taxes from the countryside was the support of the armies that every capital city required. The troops and their dependants required maintenance in a style more luxurious than that enjoyed by the majority of taxpaying peasants. Their horses required stables and fodder. All of these requirements created demands that more people were employed to satisfy and created more businesses. Entertainers, prostitutes, and transport workers as well as craftsmen of many varieties thronged these capitals. Market gardens and orchards sprang up in the near vicinities of these capitals.

The concentrated wealth of these capitals created demands for luxury goods that could only be satisfied by long-distance trade. The near simultaneous rise of the Tang dynasty and the emergence of the Arab caliphates and their consequent centralizing of much of the wealth of

China and the Muslim world created an unprecedented demand for luxury goods and stimulated a significant revival and expansion of the trans-hemispheric trade over both the inland silk routes and the marine route along the Indian Ocean littoral. This in turn led to the growth of many commercial cities along these routes. Bukhara and Samarkand are but two of these trade centers.

Likewise, the growth of the camel-borne trans-Saharan trade led to the growth of such trading cities as Kumbi Saleh and Kanem on the southern edge of the Sahara Desert.

Aside from the capital cities, there were many smaller cities. Again, these were mainly administrative and religious. Some were centers for religious pilgrimage. Mecca stands out in this respect, but so also do Nalanda, India, and Srivijaya.

Artifactual evidence from the abandoned Mesoamerican metropolis of Teotihuacan indicates that it did, exceptionally, have a large manufacturing role. Based on its abundant supply of excellent obsidian, the people of this city manufactured tools, weapons, and very fine decorations, which were evidently traded over a wide area. It was one of the few great cities with a major manufacturing function.

Cities in Early Medieval India

Cities in first-millennium India represent a new phase of urbanization in India, which can be called the third urbanization period because of the special features, differences, and notable discontinuities from the first urbanization period (cities of the Indus Valley civilization) and second

urbanization period (cities in the Ganges-Yamuna river basin in the early historic period, c. 600 BCE). Cities from 100 CE onward lack uniformity, nucleus, or a center point and also lack large city walls. Lack of these features was wrongly assumed to have indicated the decline of urban centers in India, but recent archaeological and inscriptional research has established that in the first millennium, there was a shift in the process of urbanization from the Ganges-Yamuna basin to the rest of India, which until now had been thought to play an indirect role. The cities of the first millennium are not concentrated in a single core area as noted in first and second urbanization but are distributed throughout India and acquire a regional character. The major proliferation of cities in the third urbanization of India is notable in the coastal regions of India along the Indian Ocean.

The geographical shift in urbanization can be understood in the context of increasing trade with the Arabian Peninsula and Southeast Asia with the development of the Indian Ocean network of trade routes from 300 CE onward, the decline of the Roman empire, and the development of Silk Roads trade on the northern borders of India. Major cities of second urbanization such as Taxila, Pataliputra, and Vidisa declined due to this shift. A few of the former cities, however, survived this shift in urbanization by adopting a special product of trade and cooperating with the emerging cities nearby. An example is Varanasi, an earlier religious center, now known for specialized textiles, that continued to flourish as a major city. Cities that failed this transformation declined in the Ganges basin, and hence urbanization in the first millennium indicates not only a geographical shift in the urban centers but also a shift that is economic in nature.

The Indian Ocean network heralded a new phase of urbanization in India. During the first millennium India benefited from the Indian Ocean network of trade that passed through India connecting Southeast Asia on the east with Africa and the Arabian Peninsula on the west. Hence, the evolution of cities during this period mirrors the development of this major network of ocean trade routes. In early India, rivers were the veins of communication and trade, and it is only natural that the ancient ports are located

on the rivers close to but not on the sea. These ports may have acted as a two-way communication between inland areas and the sea. In the east, the opulent Ganges Delta opened into the sea at many outlets in Bengal. Examples include Tamralipta, Chandraketugarh, and Sudkawan near Chittagong, followed by Orissa with its large fertile plain arching toward the Indian Ocean with the major port at Vishakhapatnam. The fertile deltas of the Krishna and Godavari rivers in Andhra are connected by a number of ports (Machilipatnam on the Krishna River and Srikakulam on the Vamsadhara River with the Indian Ocean), and the fertile lands of Tanjavur on the Coromandel Coast are connected to the seaports at Nagapatnam, Arikamedu, Pondicherry, etc. On the west coast, in the backwaters of Kerala, a number of seaports near the river mouths of Kerala emerged: Kulam-mali or Quilon, Fandarina or Patalyani. On the Konkan coast, ports opened toward the Arabian Sea (Goa, Mangalapura [Mangalore]), while Gujarat with its peninsula of Kathiawad (Surparaka, Cemuliya, Chaul) and Kutch open to the sea developed numerous port cities.

As opposed to the earlier period when cities were political centers founded and developed by kings, the cities of the first millennium differ in their layout and are distributed far and wide wherever trade and exchange flourished. Hence, one of the major characteristics of the cities of India is regionalism, which can be summed up as follows:

1. Regional ruling dynasties: The shift to commercial activity also goes in tandem with the shift of political diffusion. No large dynasties had their origin in the Ganges-Yamuna basin after the first half of the first millennium, and regional dynasties that evolved into powerful states in the second half of the first millennium had coastal access, with their capital cities located close to the ocean. (e.g., Gurjara-Pratiharas, Rashtrakutas, Palas, Cholas, and so on).
2. Diffuse economy: The economy was not centered in one area or product but instead was spread throughout India. Each area contributed a specialized product or trade that had its own guild organization, which in

turn connected with the all-India network of traders. The guilds functioned as individual trading and professional units on a micro-level and in their connection and network spread on an all-India basis and functioned at a macrolevel economy of India. This prevented large-scale migrations of artisans and traders who could be part of their local guild, which in turn functioned as part of the national network.

3. Regional media: Regional kingdoms, regional guilds, and regional networks sponsored and participated in regional cultural activities, which gave rise to regional languages (for example, Kannada, Telugu, Gujarati, and Bengali), regional festivals (Kumbhmela, jataras, and Tirunals in different temples), and regional gods and goddesses (Kashi Vishweshwara in Varanasi, Meenakshi in Madurai, Vittala in Maharashtra, and so on). Each leading city has its own god or goddess, language, and festival.
4. Proliferation of religion: With the development of Bhakti religion, Hinduism evolved as a popular religion, with pilgrimage as one of its central features. Religious centers proliferated in each microregion with regional characteristics while at the same time an all-India character is maintained through pilgrimage, which included major religious sites throughout India. Religious centers also evolved gradually as commercial centers, since the assemblage of a large number of travelers developed consumers markets.
5. Regional artistic and architectural styles: In tandem with the evolution of regional dynasties and merchant classes, the development of regional artistic and architectural styles is evident in the cities from 600 CE onward. The northern Indian and southern Indian musical styles (Karnataka and Hindustani music) are also accompanied by various dance styles: Kathak, Manipuri, Odissi in northern India and Bharatanatyam and Kuchipudi in southern India.
6. Rise of merchant classes: The rise of the merchant class to prominence is noticeable in inscriptions and literature. Almost all cities founded during this time have a specially designated marketplace, unlike the earlier

cities that have administrative centers as the nucleus of the city.

7. Heterogeneity: Many of these cities were cosmopolitan in nature, with inscriptional and literary texts recording that foreigners lived in major cities, such as Kanchi, Kochin, Goa on the Coromandel Coast, and the Malabar Coast.

A sharp dichotomy between the city and the village is not noticeable in this period due to the presence of social links and cultural norms extending between the city and countryside, maintained via merchant guilds and religious organizations that functioned both at the microlevel and macrolevel. In fact, the religious centers or temples were located on rivers and were close to ports, which developed a network of routes for pilgrimages that were later utilized for trade and exchange and cities proliferated on these routes. This explains the cultural role of these cities. Although the states are small and regional in character, this did not prevent an expansion of trade and religious networks operating on an all-India level, since merchants, pilgrims, and people of religion were allowed to travel freely between different states and kingdoms without restrictions. This is also the period when Indian culture spread to Southeast Asia owing to close trade links and contacts on the Indian Ocean. Dynasties such as the Palas and the Cholas sent trade embassies to China, indicating the prosperous trade and mercantile character of Indian cities.

Economic Role of Cities in Western Europe

Although the Roman empire contained many urban centers, its West European provinces remained largely rural. The cities in these areas existed primarily to house administrative centers and marketplaces. Along frontier regions, towns

➤ ABRAHAM BEN JACOB DESCRIBES THE TOWN OF PRAGUE, 973 CE

Abraham ben Jacob (Ibrahim ibn Yaqub), a merchant and alleged spy from Al Andalus (Muslim Spain), visited Prague in 961 and wrote the following in his memoirs:

“The city of Prague is built of stone and limestone, and is the greatest trading emporium of that country. To it come the Rus from Cracow and the Slavs with goods, and from the lands of the Turks come Muslims, Jews and Turks, likewise with goods and current money. And they take away slaves, tin and various pelts. . . . In Prague saddles, bridles and thick shields are manufactured which are used in their lands. Loosely woven cloths, like nets, which one cannot use for anything, are also manufactured in the land of Bohemia. They have a fixed price among them: ten cloths for a penny. They possess trunks of them. These are their wealth.”

—Joseph P. Byrne

Howard L. Adelson, ed., *Medieval Commerce* (New York: Van Nostrand, 1961), 155–156.

Romans continued to carry on trade at all levels and to staff the new royal administrations. Many of these men were from the eastern empire, and commercial ties with the Eastern Mediterranean remained intact, as both church leaders and Germanic nobility demanded the luxury items it provided. The Ostrogoths in Italy had experienced Roman civilization and did much to maintain urban life and unfettered trade through ports and along the intensive road system. In Gaul, the port cities of the Mediterranean coast and the Rhone River continued to host exchanges of European slaves and agricultural products for Eastern goods, although the volume of traffic was clearly waning as Vandal pirates raided ships and ports. Farther north, towns and town life continued to contract as buildings slowly disintegrated and roads and bridges fell into disrepair. An early medieval pattern began to emerge as artisans and agents of local landowners joined church officials and garrisons in the dilapidated but defensible town remains. The sixth century saw Justinian's Gothic Wars bring disruption and then revived trade in the Mediterranean. At the same time the Merovingian kingdom of the Franks established effective rule over much of Gaul. The relative stability of Frankish and Byzantine rule promoted minor urban development but was quickly stifled by plague and the swift successes of Islamic armies. While Muslims brought many of Iberia's towns into Islam's urban economic and cultural orbit, the Lombards drove the Byzantines from northern Italy and added little to the region's economic development. In Gaul, increasingly incompetent Merovingian rulers decentralized government administration, and what little we know of regional or local trade indicates an onset of urban decline.

Yet towns never lost their role as centers of church ritual and administration. Urban bishops and, increasingly, monasteries provided both steady demand for distant goods (incense, textiles, metalware) and a supply of local specialties that found their way to small urban markets. Pilgrims, too, stimulated some economic activity, although the great age of pilgrimage was far off. The rise of the Carolingians created a political unity of sorts and relative stability, including coinage, that encouraged internal trade from Denmark to Rome, with cities providing the essential

also served as military garrisons as well as civil administration. The tumultuous third century CE, a time marked by epidemics, civil wars, Germanic invasions, inflation, and impoverishment of the free peasantry, initiated a period of urban decline. Towns and cities shrank in area and populations and constructed walls to protect themselves from invaders. The fourth century witnessed a revival of strong central leadership and, later, the rise of local Christian leaders enjoying the emperors' patronage. In the fifth century port cities and provincial centers continued to benefit from local, regional, and international trade, but other cities, including Rome, eventually fell to invaders. Although local Roman administration often remained intact, the leaders of the Christian church and newly implanted Germanic warlords emerged as new elites. While the Germanic peoples had little use for cities other than plunder, the Christian bishops reflexively defended the Roman urban order in areas now ruled by Goths, Vandals, and Burgundians.

nodes. Trade with Byzantium picked up as Muslim territories fought among themselves, and Charlemagne's support for the church included economic concessions to the towns dominated by clerics. The Rhine, actively trafficked by Frisian cloth merchants and traders, took over the Rhone's position as the chief Gallic river network, and towns sprang up to host artisans and merchants. Yet even during this revival no large centers emerged. Italy, the most urban part of western Europe, had Rome as its largest city, which was home to only 25,000 residents. Yet the revival was enough to attract Vikings, Muslims, and Magyar raiders and invaders who sought the resources of Europe's towns. The Northmen pillaged and besieged Carolingian towns accessible by water, but they also established trading posts and towns from Ireland to the Volga. Europe's battered population built new walls around recently shrunk towns, while warrior nobility established a feudal regime in the countryside. Lasting revival only began as the threats decreased after the mid-tenth century.

City Dwellers in Dar al-Islam to 1000 CE

When the Arab conquerors expanded out of Arabia after the death of the Prophet in 632, they settled in garrison cities, which allowed them to accommodate the army and live as an elite military minority aloof from the majority of subdued peoples while leaving their administrative, social, and religious structures intact. The Jews, Christians, and Zoroastrians as adherents of earlier written revelations were recognized as a protected people (*ahl al-dhimma*), permitting them

to keep their religions as long as they paid a poll tax (*jizya*) and acknowledged Arab-Muslim sovereignty. However, within the first century, these initial attempts to sustain a dichotomy between Arabs and non-Arabs had proven to be untenable. The Arab rulers became increasingly involved in local affairs, and Arab migrations and settlements favored cosmopolitan urban centers supported by a productive agricultural hinterland.

Besides mosques and markets, Islamic cities offered their inhabitants several facilities, including libraries, hospitals, and bathhouses. Most city houses were built from bricks since wood was rare and expensive. In cities like Baghdad and Cairo people might have rented apartments in buildings of up to six floors, whereas the well-to-do could usually afford houses built around an interior courtyard with a well and enjoy the cool night breeze on a spacious rooftop terrace. Carpets covered the floors where people worked, ate, slept, and prayed, and the wealthy would also bedeck the walls with decorative rugs.

Islamic cities did not have a regular street system making all points in the city accessible; instead, the main axis routes were surrounded by cul-de-sacs and isolated districts. The population was divided according to ethnic, religious, and professional criteria and lived in juxtaposed and enclosed quarters, accessible often only through gates and some narrow streets. This reflected the social fragmentation of the population, held together not by an identity of citizens belonging to the city but instead by that of belonging to the Muslim community as a whole. The Muslim quarters were divided along occupational, tribal, and ethnic lines. The existing Jewish and Christian populations had already lived in separated communities.

The social classes represented in the cities could vary in size and proportion. The two arms of the government, the military aristocracy and the administration, stood at the top next to representatives of the Sharia, religious scholars (*ulama*), theologians, and judges. They were followed by the large class of merchants and craftsmen who were subdivided into several categories and levels. At the bottom remained the masses of have-nots who often depended on patronage or benevolence for survival. The majority of non-Muslims engaged in craftsmanship.

Some ran businesses that were prohibited to the Muslims, such as dealing with wine or money lending with interest. Jewish and Christian scholars of ancient sciences also played an important role in transmitting their knowledge to the Arabs, and their physicians enjoyed a prestigious position.

Non-Arab Muslims were first absorbed as *mawali* (clients) into the old Arab clan structure and were held to be social inferiors. As they grew in number and infused different branches of society, social tensions and class conflicts arose. By the first half of the eighth century, this led to a slow process of social change, mutual assimilation, and the creation of a Muslim, not merely Arab, empire. For example, as Basra developed from a garrison city to an administrative center with an important textile industry and trading connection to the Persian Gulf, it attracted both Arabs and non-Arabs to serve as administrators, clerks, merchants, bath attendants, weavers, and other workers and even as guards and policemen.

Markets in Byzantine Cities

Commerce was a central feature of ancient cities and remained so in Byzantium, but the location of urban markets, the nature of trade, and the role of the state underwent significant change between the seventh and eleventh centuries. The fate of cities and trade at the end of antiquity has been much debated, but archaeology is dramatically expanding an understanding of its complexity.

Late ancient cities from Egypt and Syria to North Africa incorporated commercial establishments into their monumental layout of wide thoroughfares and open public spaces, frequently

locating them in two-story colonnades along major avenues or surrounding a forum. Coins and pottery demonstrate continued involvement in a three-tier market: long-distance trade, regional commerce, and local production. Widespread remains of large amphoras used as containers for wine, olive oil, and grain and red slipware pottery are evidence of long-range trade throughout the Mediterranean, which by late antiquity was divided into separate eastern and western regions. In the eastern Mediterranean, recent excavations and surveys show continued trade and prosperity through the mid- or late sixth century in much of the relatively dense urban landscape. Regional as well as long-distance trade networks are evident, and new commercial building has also been found. Cities produced and sold a wide range of common and luxury objects, but the basic food supply, bread and sometimes oil, was controlled by the government, which supplied a free bread dole.

The seventh- and eighth-century invasions of Byzantium resulted in devastation, dislocation, and even abandonment of the urban landscape. In Egypt and the Levant, however, urban prosperity, trade, and commerce continued to thrive under Islamic rule, although urban design gradually changed. The wide colonnaded streets and open public squares began to be built over, eventually becoming narrow winding streets and *suqs*. The Byzantine heartland, in contrast, survived only by adopting a radical defensive policy whereby unwallled classical cities were abandoned as inhabitants clustered in fortresses to survive the continued invasions of Arabs and Slavs. Archaeology shows that many cities were abandoned and resettled only after the ninth century, moved to defensible hilltops, or ruralized with land within city walls used for agriculture, and there are few coin finds to suggest continued trade. Only on more protected islands, or in the ninth century, did urban centers and trade begin to recover. There is little evidence of permanent urban market sites outside the capital before the eleventh century, but periodic fairs developed. Local exchange probably used barter as much as cash.

Byzantine survival was in large part due to Constantinople's strong defenses. The state that emerged in the ninth and tenth centuries was

much more centralized in the capital. Even though it too used much of the land within its walls to raise food in the seventh and eighth centuries, Constantinople retained the monumental urban layout of late antiquity, and its palaces, monumental public squares, and large colonnaded streets survived. By the end of the tenth century, it had become a major emporium for the eastern Mediterranean, with traders from as far as Russia, Syria, and Venice gathering there.

The markets of Constantinople are described in the *Book of the Eparch*, published in the late tenth century and covering regulations for merchant guilds in the capital. The book covers 19 distinct trades and is clearly not comprehensive. Each trade had its regulated space in the city, allowing the *eparch* (governor) to exert imperial control over trading activities (bankers, notaries, silk dealers) and to ensure that perfume dealers perfumed the central processional route of the capital while also regulating businesses that generated obnoxious smells (such as fishmongers and pig and cattle dealers outside the city center). Some merchants were allowed to sell only on certain days, and foreign trade was strictly regulated, both in the housing of foreign traders and the export of imperial monopolies like silk. Sales, even of household goods, as well as fines were considered to be in coin rather than barter. The *Book of the Eparch* demonstrates the breadth of the Constantinopolitan market, from luxury goods such as jewelry and fine silks and long-distance imports such as spices to basic necessities of life, such as bread (no longer an imperial dole), wine, meat, fish, and groceries in a controlled economy.

During the eleventh and twelfth centuries, trade and markets expanded greatly in Byzantium. The commercial revolution of western Europe was reflected in Byzantium, both in the rising demand for goods within the empire and in involvement in a growing Mediterranean trading economy. Byzantine merchants were active throughout the Mediterranean in the new trade, and merchant colonies from Venice, Genoa, and other Italian cities grew up in Constantinople and elsewhere in the empire. Provincial cities became producers of products such as silk, purple dye, glass, ceramics, and soap as well as grain and food and served as centers for regional trade. Local and regional fairs expanded, possibly becoming the ancestors of the modern Greek saints day festival (*panegyris*). Byzantine commerce and Constantinople's value as an emporium for imported luxury goods were a prime reason for the involvement of westerners in the empire and the events that led to the capture of Constantinople in the Fourth Crusade.

War and Diplomacy

This essay discusses peace and war between states and empires during the Era of Expanding Regional Civilizations. War, or open armed conflict between groups, has been a human pre-occupation since the emergence of the first states. Indeed, war and taxation were among the chief reasons states were organized. States existed by monopolizing violence. Most chieftainships and every state and empire were organized to support war. The hierarchal and patriarchal structure of most societies reflected their war-making function. War was viewed as one of the most important functions, if not the most important function, of a society. The elite classes of most societies were warriors, and heroes of many societies were warriors. China was a partial exception. Kingdoms and empires during this era were normally at war or preparing for war. Periods of peace were seen as interludes between wars.

Every state and empire during this era was created and preserved by military force, and most of them fell by military defeat. States, empires, and often dynasties owed their beginnings to groups of professional fighters who gave their loyalty to an often charismatic leader with a vision of the state. Successful state builders co-opted bureaucrats and functionaries to manage the state but, in the last analysis, depended on war-making professionals to police the state and defend it against interlopers.

Professional warriors were usually highly trained and disciplined. The skills and craft needed for successful combat had to be carefully developed. Warriors were trained, much as a modern athlete, from early adolescence and for most of their lives. Indeed, the term “infantry,” the English word for foot soldiers, has the same Latin root as “infant” and derives from the early medieval use of adolescents in war. Turkish, Slav, or African children were often kidnapped to serve as slave soldiers for life.

Discipline was invested with a sacral aura in which loyalty to one’s leader or feudal lord was paramount and given religious sanction. Warriors, whether they were Roman soldiers, members of Korean *hwarang* bands, Muslim *ghazis* (frontier warriors), slave troops, or European knights, spent their whole lives and invested their whole beings in war; indeed, they had no lives outside of the warrior band to which they belonged.

Warriors, whether they were Roman soldiers, members of Korean hwarang bands, Muslim ghazis (frontier warriors), slave troops, or European knights, spent their whole lives and invested their whole beings in war; indeed, they had no lives outside of the warrior band to which they belonged.

To pay these warriors, states employed a variety of methods. The simplest way was to give each warrior a share of the plunder obtained in successful battles. This was the method used to hold together and reward so-called barbarian hordes and states in the early stages of formation. The Huns, the Germanic tribes, and the early Muslim Arabs cemented the unity of their groups by this method. Sometimes invading peoples, such as the Angles and Saxons in Britain or the Slavs in the Balkans, seized the land, killing, enslaving, or driving the native peoples off their farms. But when conquest was over in an area, it became apparent that continued plundering and enslaving the native populations would be less profitable than the exaction of tribute, and the conquerors usually set up systems of regular tribute taking. These systems or institutions of tribute taking were the basis of many states, such as the Northern Wei in northern China, the Khazar and Uighur empires, and later Kievan Rus in Inner Eurasia and a host of others.

The more successful states and empires, such as the Roman, the Northern Wei, China's Sui and Tang dynasties, the Muslim caliphates, and even the Carolingian empire (partly), paid their warriors stipends from the central treasury. In its early centuries, the Arab caliphate required its warriors to reside in specially established garrison towns, such as Kufra, Basra, Fustat, Merv, Kayrawan, and others, where they were paid stipends.

In many cases, due to the lack of economic activity or the deterioration of the central bureaucracy, it was more convenient for the central government to assign warriors territories from which they could exact tribute rather than paying stipends. The feudal system in western Europe developed from such a system. Although the West European style of feudal system was perhaps *sui generis*, similar systems developed in many regions, such as Sassanian Persia, Gupta India, and others. In Kievan Rus, Muslim lands under the Seljuks, and Japan, similar systems of remunerating warriors were used.

In most empires, there were at least two classes of armed troops. The capital army consisted of elite forces guarding the ruler, his family, and the administration. Perhaps their most important duty was to defend the ruling group against rebellions by frontier armies. The warriors in the capital armies enjoyed a relatively high social status and looked down on the frontier troops as uncouth rustics.

The frontier army's duty was to defend against barbarian invasion and often took the field, sometimes crossing into enemy territory in preemptive strikes.

A third category of troops that empires sometimes maintained were provincials, neither capital troops nor frontier guards but armies of occupation stationed in restive or rebellious provinces.

In addition to these three classes of armies, empires often maintained field armies to use as expeditionary forces in large-scale campaigns against traditional enemies. Thus, the Umayyad and Abbasid caliphates maintained at Damascus or Baghdad a large strike force that annually deployed in Anatolia against the Byzantine empire.

Armies and agriculture were inextricably linked. The feeding of the army was a basic concern of all states, and a productive farm popula-

tion was of great importance. Standing armies and their warhorses were an expensive burden for any population. These horses needed to be big and powerful to carry the warrior, clad in metallic armor. Often the horse was also protected with chain armor. These horses required special feed: grain, often oats, and nutritious hay. Fields of alfalfa were often necessary to produce feed for these war chargers.

Because of their need for a steady flow of supplies, early medieval armies were tethered to productive agricultural areas; they could not extensively campaign in lightly inhabited, devastated, or unproductive regions unless they could use river or sea transportation. The early Muslim armies, using camel transportation, had a greater range and mobility than their Byzantine enemies, who used ox and horse carts for overland transportation, but even camels needed special maintenance. Elephants, widely used as heavy cavalry by Indian and Southeast Asian armies, were the most expensive war animals to maintain.

Throughout both late antiquity and the early medieval age, land operations overwhelmingly dominated warfare, with naval operations playing a secondary role.

The Chinese were the leaders of the age in naval warfare, and they launched the largest fleets, largely on the Yangtze River but also in the East China Sea. The Battle of Paekgang (August 27, 663) off the southeast coast of Korea, in which a Tang Chinese fleet destroyed a Japanese fleet of upward of 400 ships and reportedly killed 10,000 Japanese sailors and soldiers, was one of the significant naval conflicts of the era.

The Mediterranean Sea was the arena for a continuing series of naval hostilities between the Muslim and Christian states from the 650s to the end of this period. For most of this era, Arab fleets dominated the Mediterranean, with the Christian European states in a defensive role. It was early in this time that the Arab siege of Constantinople (674–678) was broken when the Byzantines employed a new weapon, Greek fire, to burn the Arab fleet.

While Muslim fleets dominated the Mediterranean, Viking seaborne raiders ravaged European coasts. The most important naval power in Southeast Asia was the Malay thalassocracy (sea-ruling kingdom) of Srivijaya, whose ships protected Indian Ocean trade routes by patrolling the Malay straits and suppressing piracy.

The Xiungnu, the Huns, the Avars, the Turks, and other horse-riding nomads had vastly more mobility than the armies of sedentary empires due to special circumstances. First, the nomads had lighter horses that largely subsisted on grass. The nomads fought with powerful recurved compound bows rather than the lances used by the horsemen of the empires. And, importantly, the nomads were able to supply themselves with grain and fodder by raiding and devastating the agricultural lands of the empires.

In addition, for much of this period, the nomads had a technological advantage over the Muslims and the Europeans. In the early centuries

The early Muslim armies, using camel transportation, had a greater range and mobility than their Byzantine enemies, who used ox and horse carts for overland transportation, but even camels needed special maintenance.

CE, the nomads had adopted stirrups from the Chinese. Stirrups, by allowing the horseman to stand in the saddle, gave spear and lance thrusts much more force and archers greater accuracy. When the West Europeans started to use stirrups in the eighth century, a military revolution ensued. Some scholars maintain that the use of the stirrup, by making the mounted warrior supreme in medieval battle, was responsible for the culture of feudalism in Europe.

The Roman empire, the Persian empires, the Chinese empires, the Gupta empire, the Muslim caliphates, and other states of late antiquity and the early medieval age had been or would be established by military conquest. These empires expanded to a limit determined by the existing technology of communication and transportation. In most cases, it proved unfeasible to extend imperial authority more than a 90-day march from the capital. Beyond that limit, large armies could not be supplied, even though they lived off the countryside and often left famine in their wakes wherever they marched. When an empire reached its limits of communication and transportation, it established a defensive frontier. Empires often had client states, which were expected to help control peoples beyond the frontier. Thus, the Romans and the Persians were allied with Armenian kings, and each of these mighty empires had its own Arab client states.

Usually, empires erected elaborate defenses along their borders with the so-called wild forest and steppe people. These defense lines included fortified walls, such as Hadrian's Wall in Scotland; defensive walls stretching nearly 1,500 miles across northern China's grasslands; or the shorter but still impressive walls that the Persians built both to the west and east of the Caspian Sea to protect their northern frontier. The Romans used the broad Rhine and Danube rivers as their frontier, but they, like the Chinese and the Persians, were forced to keep frontier armies to garrison these passive defenses.

Sometimes the imperial forces established a no-man's-land, an uninhabited strip of territory on the frontier in which intruders would be killed or enslaved. Occasionally, imperial forces would launch forays beyond the no-man's-land as punitive expeditions or as slave-catching raids. The Spanish Muslims did this in northern Spain, central Asian Muslim armies raided Turkish tribes for slaves, and Christian Carolingian armies sent slave raiders against the pagan Slavs. If enemy raiders did manage to break through the frontier defenses, militias of local civilians were often deployed to harass the raiders with guerrilla-style tactics. In cases of invasion by large powerful enemy forces, guerrilla operations were supplemented with a scorched earth policy. This was the defensive strategy commonly used by the Byzantine empire against the Muslim forces along the Anatolian frontier.

In the third, fourth, and the fifth centuries, the frontier defenses failed in both China and the Roman empire, and barbarians poured across the frontiers to seize parts of the great empires and establish their own kingdoms, which often created demographic disasters.

The causes of these barbarian invasions were linked to environmental change. The colder temperatures and dryer conditions during the Dark Age Cold Period (ca. 250–600 CE) are said to have driven the state-

less and pastoral peoples of Inner Eurasia to attack and overrun the great sedentary states that lie on the southern rim of Eurasia.

Adverse conditions on the steppe and in the forests of Inner Eurasia were the precipitating causes, but several deep-seated factors also contributed.

First, the Germanic tribes, Huns, Hephthalites, Turks, the Xiongnu, Xianbei, Tangut (proto-Tibetan) nomads, and other barbarians had long been neighbors of the great empires, and they learned something about statecraft and war from their association. Throughout the vast areas of grassland and forest that stretched from Manchuria to Germany, these hitherto stateless peoples were (and had been for at least a century previous to this) coalescing into tribal confederations. Initially, the purpose of these confederations was probably defensive, a part of the resistance against the expansion of their great imperial neighbors and against the slave hunters common on imperial frontiers.

In their intercourse with their imperial neighbors, the barbarians traded and raided across the borders and served as border guards and mercenaries in the imperial armies. Barbarians such as Stilicho the Vandal, Alaric the Goth, or An Lushan, a person of Sogdian and Turkic ethnicity, often became high officers in imperial armies. In this way, the empires trained the stateless peoples in the skills needed for war and state formation.

Second, as the Dark Age Cold Period set in, both the Roman and Han empires were suffering from a series of economic and political crises. Cold and increasing drought produced declining harvests that resulted in famines, pestilence, and banditry. This in turn led to decreased imperial revenues and to civil wars as rival military commanders fought over the decreasing supply of public largesse. As civil wars, plagues, famines, and other natural disasters weakened the frontier defenses of the Roman empire and the Chinese states, tribal groups invaded and settled in rich provinces of these weakened empires.

In the fourth century, Xiongnu, Tibetan, and Turkish proto-Mongol and Tungusic tribes invaded, pillaged, and occupied northern China, establishing short-lived states. While northern China was experiencing invasion and desolation, refugees from northern China reestablished Chinese governments in the Yangzi Valley and farther south. Finally, after 386 one of the competing groups of barbarians, the Xianbei Touba, established itself as the Northern Wei dynasty that, by 439, conquered all its rivals and established rule over all of northern China.

The Touba, who were instrumental in establishing a Sinicized form of Buddhism in northern China, were assimilated into Chinese culture, and with their rule, stability returned to northern China. China continued to be divided, into a northern and a southern empire, until the Sui dynasty reunited it in 589.

The Roman empire succumbed to barbarian onslaughts later than the Chinese states, but in the fifth century, Huns and Germanic

Finally, after 386 one of the competing groups of barbarians, the Xianbei Touba, established itself as the Northern Wei dynasty that, by 439, conquered all its rivals and established rule over all of northern China.

tribesmen devastated the empire's western half. Germanic tribes erected kingdoms in the western provinces, similar to the way barbarians had established kingdoms in devastated northern China. In the Roman world, as in the Chinese, the old culture continued in the unconquered half of the empire. While the southern Chinese empire preserved traditional Chinese culture, likewise the Byzantine, or eastern Roman, empire was the sanctuary for classical Greek and Roman culture.

Sassanian Persia and Gupta India were also subjected to barbarian invasions during the early centuries of this period. The Persians built a series of defensive walls, extending several hundred kilometers east and west on both sides of the Caspian Sea to guard against invasions of pastoral nomads, but when barbarians did invade, they came from the east, beyond where the fortifications ended. These barbarians, called Hephthalites, or White Huns, conquered much of central Asia by 350. In the next half century, they conquered Afghanistan and invaded India, seizing the northwest including the fertile Punjab. Although they hastened the demise of the Gupta empire, they were soundly defeated by a coalition of Hindu rulers about 550 CE. The Hephthalites raided Persian cities and in 484 defeated the Sassanian Army, killing the emperor. For decades, the Hephthalites forced the Sassanians to pay tribute, but in the early sixth century the Persians destroyed the Hephthalite army and killed the Hephthalite king.

Religion is said to have a role in causing many conflicts, and it cannot be denied that hostilities between Christians and Zoroastrians played a role in the Byzantine-Sassanian conflict or that the wars by which the Arabs conquered their empire had a strong religious current, as did the Carolingian wars against the pagan Saxons and Slavs. But one of the most important factors promoting warfare involved the elites' understanding of history and their role in it. Many civilizations, particularly Western and Indian civilizations, understand their history as being shaped by conflict, and their national epics and religions reflect this. Some elites and rulers practiced historical mimesis (recreation of an imagined and idealized historical reality) by attempting to replicate the roles of their cultural heroes.

The view of history as being a tale of conflict has a venerable age. The Greek epics, the *Iliad* and the *Odyssey*, and also the two Indian epics the *Mahabharata* and the *Ramayana* glorify war. Religions, particularly Zoroastrianism, Christianity, and Islam, view cosmic history as struggle between opposing forces. Christianity teaches about Armageddon and the apocalypse. In such a cultural milieu, to be a warrior is glorious.

Wars can develop their own momentum so that a conflict can become a series and can continue for centuries after the original cause is forgotten or becomes irrelevant. A war starts over a real or imagined cause, and one side defeats the other. The defeated party, humiliated, bides its time and marshals its strength until it can retaliate. In this way, one war begets another, and the cycle continues.

The series of wars between the Roman empire and the Parthian/Sassanian dynasties of Persia that lasted six centuries is such a cycle. In this long struggle, both sides thought that they were filling roles in a historical drama, reaching back to the conflict between the Trojans and the Greeks and continuing through the Persian Wars of which Herodo-

tus wrote. Alexander the Great's conquest was but one act in the ongoing drama, but it exerted a powerful fascination over the Romans, who saw themselves as the successors of the Classical Greeks. During the 600 years of conflict between Rome and Persia, there were long periods of peace during which the two sides traded with each other and enjoyed amicable relations, but once or twice in each century, sometimes more often, a Roman or Persian ruler would revive hostilities. Both the Persian empire and the Roman empire maintained highly trained professional armies whose leaders sought prestige and renown in war. They were nurtured on a history and mythology that served to ennoble and continue the multigenerational conflict.

The final war between the two lasted a quarter of a century. Its principal result was to fatally weaken both empires, making them easy prey for the rising Muslim forces. The Persian empire was destroyed, while the Roman (Byzantine) empire lost all its richest provinces.

After the Muslim conquest of the Sassanian empire the drama of conflict continued, with the Muslims filling the place of the Persians and the Romans morphing into generic Christians. The Arabs went from success to success, and with astonishing speed their armies conquered a vast empire. By 711, their conquests extended from Spain in the west to northwest India in the east and from the Oxus (Amu Darya) in central Asia to the Second Cataract of the Nile in the south. The expansive momentum of the Arabs reached its zenith in 751 when an Arab army destroyed a Chinese force at the Battle of the Talas River in central Asia. In Europe, the Arab tide had already begun to ebb with an Arab defeat at the Battle of Tours-Poitiers (732). And in spite of two prolonged and hard-fought Muslim sieges of Constantinople (674–678 and 717–718), the Arab surge failed to destroy the Byzantine (Roman) empire.

By the mid-eighth century the Arab assault subsided, but indecisive guerrilla struggles continued on Muslim frontiers in Spain, Sicily, southern Italy, Anatolia, the Caucasus, and northwestern India.

Only on the frontier between Muslim Egypt and Christian Nubia was there a more or less durable peace.

The explosion of Arab imperialism occurred with a suddenness and speed that were remarkable. To explain its explosive nature, one must point to the internal weakness of both the Byzantine and Sassanian empires and the simultaneous unification of the Arabs with the meteoric emergence of Islam. The passion and zeal of the Muslim Arabs were rewarded by early spectacular victories that not only electrified the Arabs but also enriched many of them. New recruits flooded into the ranks of the Arab armies, and more plunder rewarded the warriors. But as new recruits joined the forces they also expected rewards, and this created pressure for more conquests. But after a century, most of the areas that could be easily conquered were conquered, and the storm of Arab conquest was over. Turks and Berbers, but not Arabs, would resume Muslim expansion, especially in India and West Africa after 1000 CE.

Compared with the wealth of information we have about wars during late antiquity and the early medieval age in the Afro-Eurasian ecumene, our knowledge about conflicts in the Americas during that time is slight except for the Mayan cities. Archaeologists tell us that at the outset of this period, the bow and arrow started diffusing south from the

The Moche of northern Peru tell us about their way of war on their ceramics: they fought with clubs instead of bows and arrows, they fought neighbors for territory and for commodities such as coca, and they dismembered their prisoners, perhaps for ritual cannibalism.

Arctic peoples, to whom it had been introduced from Siberia about the turn on the Common Era. By 500 CE, this weapon was common in North America. Though the peoples of Mesoamerica may have had knowledge

of the bow, it was not important in their warfare. Mesoamericans as well as the peoples of the Andes fought with clubs, spear-throwing atlatls, and obsidian knives. The Moche of northern Peru tell us about their way of war on their ceramics: they fought with clubs instead of bows and arrows, they fought neighbors for territory and for commodities such as coca [cocaine is extracted from coca leaves], and they dismembered their prisoners, perhaps for ritual cannibalism.

The Maya of Mesoamerica inhabited numerous city-states whose rulers boasted of the wars in which they humiliated rulers of neighboring cities. From 400 to the crash of Maya civilization in the ninth century, two cities, Calakmul and Tikal, fought wars with each other for supremacy in Maya-land, similar to the long conflict between Persia and Rome.

Conflicts were not always between states; often civil wars disturbed the internal tranquility of states. These civil wars often concerned disputes about the succession to the rulership of a state. All dynasties, whether Chinese, Arab, Byzantine, or other, began and ended in civil wars.

Despite the frequency of wars and the endemic hostility between states, there were also long periods of peace between most peoples during this period. Trade, travel, and other kinds of peaceful intercourse between states prevailed during the periods between hostilities. Although the era of full-time professional diplomacy in which ambassadors were permanently posted in neighboring state capitals was still many centuries in the future, most states did conduct sporadic diplomacy with each other.

Embassies were often large expeditions, as interested in trade as in diplomatic relations. The Japanese sent eight large embassies to the Tang court to establish diplomatic relations, to trade, and to bring students to study Chinese technology and culture. The Sui and Tang governments sent military expeditions to the oasis kingdoms on the Silk Roads whose mission was to conduct diplomacy and to cement alliances, sometimes at the point of the sword. Often, states exchanged high-status hostages as pledges of friendship and amity. Dynastic marriages between neighboring states were also frequently arranged. The Tang and other Chinese dynasties sometimes resorted to the practice of awarding Chinese princesses to barbarian rulers to promote peace or to cement an alliance.

Although it is difficult to determine whether the Age of Expanding Regional Civilizations had more or fewer destructive conflicts than later eras, a plentitude of war darkened human existence and destroyed human hope during this era.

■ Introduction: War and Diplomacy in Eurasia, 300–632

For nearly seven centuries (the first century BCE to the seventh century CE) two great empires, the Roman and the Persian, coexisted side by side in the Mediterranean region and West and Southwest Asia. Their relations were often peaceful, but in almost every century the peace would be disturbed by protracted wars between the two giant states. While these empires were relating to each other with often more than guarded hostility, “barbarian” peoples on their northern frontiers threatened both. Both empires maintained heavily armed forces to defend their northern frontiers as well as their frontier with each other. For each of these great powers, the burden of maintaining these powerful frontier armies was a serious drain on their prosperity. Not only were these armies crushingly expensive, they were, at times, serious threats to the internal stability of the empires they were meant to protect.

From the fourth to the mid-seventh centuries, the pastoral and other peoples north of the Roman, Persian, and Chinese frontiers were in motion. In the fourth century, pastoral groups poured through Chinese defenses and occupied northern China, establishing their own “barbarian” regimes. By the mid-fifth century, one of these pastoral groups, the Toba Turks, imposed its rule over all of northern China as the Northern Wei dynasty that was, within less than a century, Sinicized and assimilated into Chinese culture.

On the western edge of Inner Eurasia other “barbarian” groups invaded the Roman empire in the late fourth century and throughout the fifth century, toppling Roman authority and erecting their Germanic kingdoms in the western half of the empire. The eastern half of the Roman empire, which we know as the Byzantine empire, survived and continued to pursue the ancient quarrel with the Persians.

During the late fifth century and much of the sixth century, the Persians were having their own problems with northern “barbarians,” the Hephthalites (White Huns). The Hephthalites moved out of central Asia in the fifth century and erected a large state centering in modern Afghanistan but also including territories in the

Oxus River and Ferghana valleys. The attention of Sassanian Persians was focused on the Hephthalite threat through most of the fifth century and much of the sixth century, but after the Sassanian king Khosrau decisively defeated the Hephthalites in 557, the Persians were free to renew their quarrel with the Romans.

The Roman-Persian conflict ended with a climactic war lasting a quarter of a century that left both empires exhausted and easy prey for the newly emergent Muslim Arabs.

Barbarian Invasions of China, India, and the Roman Empire, 300–650 CE

Developments in the central Asian steppes in the early fourth century CE triggered the onslaught of invasions by so-called barbarians through much of Eurasia for the next three centuries. Climate change in the central Asian steppes, which led to decreased rainfall and grass stocks, forced pastoralist peoples, most notably the Huns, to seek more hospitable climes for their livelihoods. Most of these barbarian migrations were triggered by the pressure exerted by the Huns, who were a confederation of Eurasian tribes from the steppes of central Asia. Through their use of advanced weaponry, rapid mobility, and battlefield tactics, they achieved military superiority over many of their enemies, subjugating the peoples they conquered. In the process, these groups of people who had been kept at bay by the older and more sophisticated and established civilizations were brought into open conflict. While some of these groups had been successfully co-opted by either the Romans or the Chinese in prior centuries,

BARBARIAN INVASIONS, CIRCA 450

other groups felt compelled to engage in open warfare in order to secure land and partake in the benefits of their more sophisticated imperial neighbors.

More than 600 years before the eruption of the Huns, the Xiongnu, whom some historians see as ancestors of the Huns, had threatened the China as early as the second century BCE. Han westward expansion pushed the Xiongnu into the central Asian steppe. However, the outlying barbarian peoples around Han China also began entering China in the east for its wealth and arable lands. Climate change in the steppe compelled these ethnic groups to seek their fortunes as the Han fell into decline in the third century CE. The Han state had collapsed in 220 CE, and China was only briefly reunited by the Jin dynasty in 280 CE. However, civil war wracked the Jin dynasty, and similar to the Roman empire, it was barbarians who had been settled in previous years who took advantage of the situation. In 311 CE descendants of the southern Xiongnu seized Emperor Huai and the capital of Luoyang. His successor, Emperor Min, was taken

in Chang'an in 316 CE, and although Jin rule continued in the south, Chinese rule over the north ceased (until 589 CE).

The various states founded by Xiongnu factions were not the chief power in the appropriately named Sixteen Kingdoms Period. Barbarian groups from the Di, Qiang, Jie, and Ba-Di also founded kingdoms. Most important were members of the Xianbei confederacy that had grown in power in the third century. In 258 CE the Chinese Jin dynasty had even used them as allies against the Xiongnu. They established 5 of the 16 states of this period, and this culminated when the Tuoba Xianbei's Northern Wei dynasty (386–534 CE) brought the north under stable rule. The Northern Wei was increasingly sinicized (assimilating Chinese customs and culture), moving their capital to Luoyang, adopting Chinese clothing and names, converting to Buddhism, and using Chinese administrative practices and personnel. The nomads-turned-Chinese-rulers were themselves forced to fight numerous battles on their northern frontier against peoples from their former Mongolian homeland. In 524 CE a rebel-

THE SACK OF ROME

By the fifth century CE the city of Rome had ceased to be the center of political authority. Emperor Honorius (r. 395–423 CE), for example, ruled from defensible Ravenna, but Rome's sack by the Visigoths in 410 CE was nevertheless a powerful symbol of the decline in Roman authority. However, it was not simply a case of Roman against barbarian. Numerous barbarian *foederati* fought for the Romans, and even Honorius's chief general Stilicho was a Vandal.

Alaric (r. 395–410 CE) and the Visigoths had helped Emperor Theodosius I (r. 379–395 CE) put down a rebellion in 394, but the Goths felt that they had been inadequately rewarded and rose against the empire, declaring Alaric their king. They first marched against the eastern Romans, plundering Greece, until Stilicho crossed from the West to confront them in 397. The Goths then traveled to Italy, but Stilicho was again responsible for driving them out in 402. In the fluid political situation, Alaric became the western Romans' ally

against the eastern empire in 407, but court politics led to the murder of Stilicho and of the families of many *foederati*. As a result, many went over to Alaric, and the Visigoths attacked the city of Rome three times in the following years. The first time (408) the Senate was able to ransom the city; the second time (409) Alaric set up a puppet emperor, Attalus. The third time the Visigoths attacked in earnest, storming the city on August 24, 410. The city was looted, but the Christian Goths spared the churches, and only a few areas of the city were damaged by fire. According to Procopius's *History of the Wars*, in Ravenna a eunuch rushed to inform Emperor Honorius that “*Roma* has died!” Honorius was horrified until he discovered that the eunuch was talking about the city and not his pet rooster of the same name. Alaric himself died soon after, and the sackers of Rome renegotiated an alliance with Rome, settling in southern Gaul (France) in 418 CE.

—Jonathan Bruce Markley

lion by the less sinicized military brought serious difficulties, and the state split in 534 CE. Except for a brief period under the northern Zhou, the region would remain divided until the Sui dynasty reunited north and south under Chinese rule in 589 CE. Similar developments would ensue in the West with nomadic invaders.

Roman relations with its Germanic neighbors to the north had been somewhat stable in the first and second centuries CE, with sustained legion foray into Germanic lands to quell potential aggression. In the second and third centuries, Roman military strength in its North European provinces had significantly deteriorated, and this necessitated the greater use of Germanic mercenaries along the borders who served Rome in exchange for being allowed to settle within the empire. However, by 376 CE, the Visigoths (western Goths) crossed the Danube and entered the Roman empire. This was not, however, an invasion. The Gothic tribes were fleeing the Huns (who had swept out of the East) and sought refuge in the empire. However, relations broke down, and in the resulting Battle of Adrianople (378 CE) the eastern Roman

(Byzantine) Army was obliterated. Negotiations initially led to a treaty in 382 CE making them *foederati* (federates) of the empire. The Goths had converted to Arian Christianity and, like many other barbarians, sought to emulate Roman administration in their states. The most successful of the post-Roman kingdoms were those of the Ostrogothic (East Gothic) king Theodoric in Italy (489–526 CE), the Visigoths in Spain, and the Franks in Gaul.

Although they often provided troops to Roman armies, the Huns themselves remained a threat, particularly under Attila (r. 434–453 CE). The eastern Roman empire succeeded in purchasing peace with the Huns with gold, while in the West, Roman forces, allied with Goths and other tribes, combined to oppose the Huns. Ultimately, the Huns were defeated at the Battle of Chalons (also known as the Battle of the Catalaunian Plains) in 451 CE by a Roman-Visigothic coalition, which crushed their power and led to their decline. They disappeared as a major force by the mid-fifth century.

Many other tribes crossed into the empire including the Burgundians, who seized eastern

Gaul; the Lombards, who settled in Italy in the sixth century CE; and the Angles and Saxons, who were invited to Britain to aid in its defense and dominated the south and east of England by the sixth century. The Vandals crossed the Rhine in 406 CE, establishing a kingdom in North Africa for a century (430–533). Others such as the Alamanni and the Alans played lesser roles in these invasions. Slavic Avars were the major threat in the sixth and seventh centuries, even besieging Constantinople in 626 CE.

The history of the Goths is in many ways typical of what earlier historians termed the “barbarian invasions.” Various tribes driven by extraordinary circumstances entered the empire and engaged with Roman authority in a complex web of cooperation and conflict. The Romans signed treaties, recruited troops, and often granted permission for settlement. It was a dangerous path. The last western Roman emperor was overthrown in 476 CE by his barbarian general Odoacer, but even he sought legitimacy by asking Constantinople to recognize his authority. However, the Romans lacked the military and economic means to expel the various peoples, and they had little choice but to make necessary compromises. For example, rather than directly intervene against Odoacer, the Ostrogoths invaded Italy with Constantinople’s blessing in 490 CE. Byzantine (East Roman) emperor Justinian’s (r. 527–565 CE) general Belisarius (500–565 CE) fought long wars in the West, and although he defeated the Ostrogoths in Italy and the Vandals in Africa, it is doubtful that his campaigns brought any adequate return. Justinian’s policy of bribery and diplomacy on the Balkan frontier was less popular but also more economical. The Visigoths established their kingdom, which ruled Spain until the Muslim Arabs conquered it in 711 CE. The most enduring of the Barbarian kingdoms was that of the Franks in Gaul, which eventually became the Kingdom of France. The Angles and Saxons in Britain established a multitude of little states that, by the ninth century, coalesced into one kingdom.

While the Indian subcontinent had a similar relation with external nomadic invaders, it would be far more successful in resisting the

threat by these pastoralist peoples seeking lands at their expense.

In the Indian subcontinent, the Gupta state came under increasing pressure in the fifth century CE from invasions out of the northwest by a group usually known as the Hunas (sometimes also known as the White Huns). Their connection to the Huns of Europe, the central Asian Hephthalites, or Greater Yuezhi, with whom they have been identified remains unclear. The scale and consequences of their attacks seem to have been more limited than those in the West and Far East. Skandagupta was able to repel an attack in 458 CE, but the Gupta disunity contributed to their loss of control of the northwest by 510. The Hunas were particularly hostile to Buddhism, and the work of Buddhist scribes probably contributed to the hostility of the tradition concerning them. Toraman and his son Mihirakula maintained Huna power in northwestern India for a time, but they were driven into the Kashmir region by local coalitions prior to 550. Other Huna rulers followed, probably ruling territories farther to the north in modern Afghanistan. A Sassanian-Turk coalition destroyed them sometime after 557, after which they disappear from historical records. Tradition maintains that Hunas who remained in India were assimilated into the local culture, but attempts to link the Hunas with modern Indian groups such as the Rajputs and Gujars are disputed. The collapse of Gupta rule seems to have been due to internal difficulties (perhaps exacerbated by war costs), and unlike in China or western Europe, the power vacuum was not filled by barbarians but instead by groups from within what had been the Gupta state, such as the diminished kingdom ruled by Harsha (606–647 CE), a grandson of the Gupta royal house.

Wars between Rome and Persia

The beginning of the fourth century heralded enormous changes in the Roman world that had important ramifications for Persia. First, during the reign of Constantine the Great, the Roman empire began its transformation from a polytheistic into a Christian empire. As Christian bishops (seeking the elevation of Christianity) grew in power throughout the empire, so did an inherent distrust of non-Christian faiths including the Zoroastrianism of the Persians. Although the Roman and Persian empires had been in periodic conflict since the first century BCE, the rise of Christianity contributed to their enmity as their competing faiths later became an important element of the transformation of their hostilities into holy wars. The early fourth century also witnessed the relocation of the center of Roman authority to the east as the city of Constantinople (founded by Constantine in 330 CE) grew to even greater imperial importance than Rome. Although the western half of the Roman empire maintained an emperor until 476 CE, the emperors of the eastern Roman empire (Byzantine empire) held greater prominence and, usually, economic and military power. This new focus and shift of Roman power to the east, bolstered by an increasingly militant faith, led to intensified hostilities between Romans and Persians until the demise of the Sassanian (Persian) empire in the seventh century.

Roman eastward expansion during the later part of Constantine's reign ensured greater hostilities with Persia and a legacy of campaigning in Mesopotamia for Constantius II, his son and successor. Constantius II carried on his father's efforts in the east without delay, as less than a year after his father's death he had made his headquarters at Antioch for annual campaigns

Roman emperor Julian II, “the Apostate,” became one of the most notorious and well-documented emperors of the later Roman empire. Julian, like many emperors before him, invaded the Persian empire—with disastrous results. (Vanni Archive/Corbis)

against the Persians, lasting until 346 CE. Following in the precedent of Constantine and his son, other Christian Roman emperors continued hostilities periodically against the Persians throughout the fourth century. Even the last pagan Roman emperor, Julian II (Julian the Apostate), made war against the Persians an early priority of his short reign. He later died during the war from a spear wound in the Battle of Samarra in 363 CE.

The fifth century was generally a more peaceful period in Roman and Persian relations (in comparison to the fourth and sixth centuries), as the neighboring empires resorted to military conflict on only two occasions. The first war broke

➤ ANTIOCHUS STRATEGOS—THE PERSIAN CONQUEST OF JERUSALEM, 614 CE

Long-running hostilities between Byzantine Christians and Zoroastrian Persians led to the Persian conquest of Jerusalem in 614. The following account by the Byzantine monk Antiochus Strategos, a resident of Jerusalem and eyewitness of the event, is reflective of the deep animosity resulting from centuries of hostility that existed between the two sides as well as the despair that Byzantine Christians must have felt at losing control of the Holy City.

“Meanwhile the evil Persians, who had no pity in their hearts, raced to every place in the city and with one accord extirpated all the people. Anyone who ran away in terror they caught hold of; and if any cried out from fear, they roared at them with gashing teeth, and by breaking their teeth on the ground forced them to close their mouths. They slaughtered tender infants on the ground, and then with loud yelps called their parents. The parents bewailed the children with vociferation and sobbing, but were promptly dispatched along with them. Any that were caught armed were massacred with their own weapons. Those who ran swiftly were pierced with arrows, the unresisting and quiet they slew without mercy. They listened not to the appeals of supplicants, nor pitied youthful beauty nor had compassion on old men’s age, nor blushed before the humility of the clergy. On the contrary they destroyed persons of every age, massacred them like animals, cut them into pieces, mowed sundry of them down like cabbages, so that all alike had severally to drain the cup full of bitterness. Lamentation and terror might be seen in Jerusalem. Holy churches were burned with fire, others were demolished, majestic altars fell prone, sacred crosses were trampled underfoot, life-giving icons were spat upon by the unclean. Then their wrath fell upon priests and deacons; they slew them in their churches like dumb animals.”

out in 420 CE due to disagreements over Byzantine unwillingness to return Persian Christians who had sought refuge in the Byzantine empire from persecution. The Persians, in turn, took Roman gold miners working in Persian territories as hostages, prompting a Roman invasion. The Romans experienced considerable early success, which soon won them a favorable peace agreement. The second war broke out as the result of a Persian invasion of Roman territory in Armenia in 440 CE. The Persians attacked during a period when the Roman empire was experiencing numerous military difficulties, as the city of Carthage had been lost to the Vandals less than a year earlier in 439 CE. Consequently, the Romans were anxious to come to terms, and the Persians soon withdrew when they were paid off.

The sixth century was a period of intensified hostilities between the Persian and Roman empires that began when the Persians under King Kavadh I again invaded Armenia in 502 CE. Although Kavadh wished to expand the boundaries of his empire, he ended up winning very little, as the Romans under the leadership of Emperor Anastasius I effectively fought him to a draw. The war did not formally end until 506 CE when both sides agreed to a truce that resulted in 20 years of peace. The next period of conflict began in the latter part of Kavadh’s reign when he tried to force Christian Iberians (located primarily in the Transcaucasus region and upper Mesopotamia) to become Zoroastrians. Although the Iberians were under Persian rule, Roman forces interfered with Persian efforts, provoking a war that lasted from 527 until 532 CE. With the death of the Persian king in 531 came serious negotiations for peace and the formal signing of a truce in 532 CE. The peace was largely agreed to because Kavadh’s successor, Khosrau I, wanted the opportunity to stabilize his newly acquired empire.

In 540 CE hostilities broke out again when Persia invaded Syria and attacked cities in Mesopotamia and Byzantine Armenia. The Byzantine response was delayed by the fact that this was a period in which Justinian I’s most important general (Flavius Belisarius) was fighting in the west and had to be quickly recalled to the east to deal with the Persians. After five years of indecisive conflict, the Byzantines and Persians nego-

tiated a truce in which the Persians agreed not to attack Byzantine territory for the next five years. Yet mistrust and hostilities between the two empires continued during this period because of events happening elsewhere. The Romans wanted control of the kingdom of Lazica (in present-day western Georgia) as a barrier against Persian advance from Iberia to the Black Sea. The kingdom was under the control of the Persian empire, but its inhabitants were Christians. The Lazic king, Gubazes II, sought the assistance of Byzantium when he revolted against the Persians in 548 over fear that Emperor Khosrau I intended to convert his people to Zoroastrianism or replace them with more loyal inhabitants. These actions resulted in another lengthy and indecisive war that lasted until a truce was signed in 557 CE followed by a more substantial peace agreement in 562 CE in which the Persian ruler Chosroes I recognized Lazica as the Byzantine vassal state in exchange for annual payments of gold.

The final outbreak of war, and perhaps the most significant for the future of both empires, began in 602 CE. This war with Persia was in one way similar to the later crusades in that it was promoted by Byzantine leaders as a holy war between Christianity and Zoroastrianism. The war began when Khosrau II (r. 590–628 CE) attacked the Byzantine empire during a succession crisis in which the Roman emperor Maurice (r. 582–602 CE), an ally to Khosrau, was murdered by the usurper Phocas (r. 602–610 CE). The Persians had considerable early success during Phocas's reign, as they plundered Syria and Asia Minor. Persian successes initially continued with the ascension of Heraclius to the Byzantine imperial throne in 610 CE, as Damascus was captured in 613 CE and Jerusalem was taken in 614 CE with the True Cross taken away in triumph. Persians then occupied Egypt in 619 CE and conquered the city of Alexandria in the same year.

Much of the reason for Persia's early success was the result of internal dissension in the Byzantine empire as well as the distraction of dealing with other threats posed by the Avars and Slavs. Yet Byzantine fortunes began to change in 622 CE when under Heraclius's inspired leadership they won a decisive battle over Persian

forces at Issus and were able to fend off a combined Persian-Slav-Avar attack on Constantinople in 626 CE. It was during this successful defense of Constantinople that Heraclius demonstrated his skill as a military commander. Confident in the city's ability to hold out under siege, Heraclius took the fight to his enemies as he sailed through the Black Sea to attack Persia from behind. Heraclius and his army won several important battles as they made their way through Persia, culminating in a crushing victory over the Sassanian army in northern Mesopotamia in December 627. Heraclius then began to make his way toward the Persian capital of Ctesiphon. On news of Heraclius's approach, Persian leaders assassinated Khosrau II, and his successor Kavadh II (r. 628) made peace with Heraclius by restoring Byzantine territories won in the early half of the war.

This conflict ultimately exhausted both the Byzantines and the Persians economically, militarily, and psychologically, and, as a result, neither was well prepared to deal with the rise of Islam in the decades that followed. Early Islamic armies had an especially devastating impact on the Persians, as they quickly conquered and consolidated the Persian empire under the Islamic caliphate by the middle of the seventh century. The Byzantine empire survived the early Islamic onslaught (barely fending off attacks on the capital city of Constantinople in 674 and 717 CE) but lost control of enormous territories in North Africa and Syria. The survival of the Byzantine empire boded well for Christian Europe, as the Byzantine state served as a buffer to Arab (and later Turkish) invasions until its fall to the Turks in the fifteenth century.

Overview of Maritime History

From the perspective of maritime commercial and technological and naval history, the outstanding changes of the centuries from 300 to 1000 were the gradual decline of the maritime primacy of the eastern Mediterranean and the growing volume of trade across maritime Asia. Egypt, the Levant, and the Aegean had dominated the Mediterranean as a whole for the previous 2,000 years. In their place arose the central and western Mediterranean commercial and naval powers—with the Muslim faith giving way to Christianity—of Italy and Spain, which emerged around the tenth century. These set the stage for the economic integration of western and northern Europe, without which the transoceanic expansion, colonization, and economic globalization of recent centuries would have been impossible. Simultaneously, the trade of Asia, with its enviable diversity of rare and exotic flora and fauna, became ever more attractive for those both within its sphere and beyond it.

Northern Europe underwent a period of violent transformation as Christianity and trade penetrated northward beyond the limit of what had been the Roman empire and secular rulers fought for precedence, often in the guise of religion. The east-west divide of northern Europe was lessened thanks in large part to the Vikings of Scandinavia, who had no sails until the seventh century and no Christianity until the tenth century. Although infamous for their violent raids, the Vikings laid the foundation for vibrant east-west commerce, and they stimulated north-south trade via the Russian rivers between the Baltic Sea in the north and the Caspian, Black and Mediterranean seas in the south. Their westward ventures bore them to the British Isles, southward along the coasts of France and Spain and into the Mediterranean, and across the North Atlantic to Iceland, Greenland, and eastern Canada. In their achievements we can see the dynamism of northern maritime Europe from which would spring, when crossed with the maritime traditions of the Mediterranean, the world-girdling enterprise of the 1400s and later.

The littoral of Asia and East Africa—bounded by the Indian Ocean, the Indonesian archipelago, and the South and East China seas—underwent

comparable changes, characterized broadly by the spread of Buddhism in the east and of Islam in the west. The written history of the western Indian Ocean prior to the rise of Islam is sparse. The two principal imperial powers with an interest there were the Byzantines, who controlled Egypt and much of Arabia and therefore the Red Sea, and the Sassanian Persians, whose territory embraced the Persian Gulf and whose seafarers traded to East Africa, India, and China. Muslim armies overthrew the Byzantines and the Sassanians in the Middle East by 650, and Muslim merchants—including both Arabs and converted Persians—began sailing along their old trade routes. Muslim mariners also began to establish enclaves on the coast of India, where through intermarriage with low-caste Hindus there evolved creole communities of Mappilla Muslims that flourished until the sixteenth century.

The existence of foreign trading communities of both newly arrived or converted Muslims and of more established Jews, Zoroastrian Persians, and Nestorian Christians became especially important for southern India's overseas trade as Hinduism superseded Buddhism and Jainism. After the eighth century, more conservative observance of purity rites led to a diminished involvement in overseas trade by Hindu traders.

In the first millennium CE, commerce across the Bay of Bengal between the Dravidian kingdoms of south India and the Southeast Asian states flourished. Through this trade, Indian civilization, including its Hindu religion, cultural norms, architectural styles, music and dance patterns, and material culture spread to Southeast Asia. The view that such cultural norms were imposed from India in the course of a medieval colonial project has been largely debunked. It is clear that while certain imports were entirely new to Southeast Asia—writing, for example, in a variety of scripts from different parts of India—developments in Southeast Asia were not simply a function of alien influence. That the states of Southeast Asia were on a more or less equal footing with their Indian contemporaries can be seen in their lavish endowment of monasteries and temples at home and in India, the latter probably intended as much for commercial and political as for spiritual benefits.

Perhaps the most ambitious sea-based military campaign of the age was launched by the Chola kingdom of southern India, which in the 1020s ventured north to Bengal and subsequently east against the kingdom of Srivijaya. Sailing more than 1,500 miles across the Bay of Bengal, the Cholas captured 13 cities on either side of the Malacca Strait on the Malay Peninsula and Sumatra, including Srivijaya, Palembang, and Kedah and perhaps in Burma.

From the fourth to sixth centuries, pressure from hostile neighbors in central Asia caused political fragmentation in China. Southern states on the South China Sea began to pursue trade with Southeast Asia. This proved to be the foundation of an overseas trade that reached its apogee during the Tang dynasty (618–907), when the flow of goods and ideas, notably Buddhism, from India and farther west was at its peak. From China, Buddhism and other material, cultural, and religious aspects of Chinese civilization passed to Korea and via the Korean kingdoms to Japan.

South of the sphere of Persian influence, mariners probably originating from Java crossed the Indian Ocean to Madagascar, most likely between the second and fourth centuries. There they introduced a variety of goods and plants that were subsequently brought to Africa proper. Most notable of these are the water-yam, taro, plantains, and bananas, which have long since become staples in other parts of the world, notably the Americas.

Far removed from Eurasia, Pacific islanders finished their settlement of Oceania. Voyagers from Tahiti and the Marquesas Islands sailed southeast to Easter Island—the most remote island on earth—in the fourth century, and a century later they crossed the equator to settle Hawaii. At some point in the next few centuries Polynesians reached South America, returning to Oceania with the sweet potato. Their last major discovery was of New Zealand, first settled in the tenth century. Around the same time, bearers of the Thule culture spread eastward across Arctic North America from Alaska to Greenland.

THE BOOK OF THE WONDERS OF INDIA

Commerce and religion often go hand in hand, as shown in a story from Buzurg Ibn Shahriyar's tenth-century *The Book of the Wonders of India*, a celebrated Arabic compendium of sea stories. In 922 an Omani merchant named Ismail landed on the coast of East Africa near Sofala, where his crew began bartering with the locals. When the king boarded the ship to see off the merchants, Ismail kidnapped him and put him with the other 200 slaves already aboard. Several years later Ismail returned and was brought before the ruler, his former captive. According to the unnamed king, after living as a slave in Basra and Baghdad and converting to Islam, he escaped his owner and made his way to Mecca and Cairo. From there he headed down the Nile and eventually reached the Indian Ocean and boarded a vessel that brought him home. His people had agreed not to choose a new king until they had definite news of his fate, so he resumed his throne. "Like myself," he told Ismail, "they embraced the religion of Islam. . . . And, if I have forgiven you, it is because you were the first cause of the purity of my religion." The king asked the Omani to "let Muslims know that they may come here to us as to brothers, Muslims like themselves." His people's adoption of Islam had a practical side, and the king could promote their faith in the same way a business might post a sign saying "Arabic spoken here."

■ Introduction: Conflicts Relating to the Emergence of Islam

The emergence of Islam and the creation of the Arab Islamic empire destroyed the Persian empire and left the Byzantine (East Roman) empire a weakened rump of that erstwhile mighty great power. The two great empires of Persia and Byzantium climaxed their seven centuries long series of intermittent conflicts exhausted, their populations alienated and their treasuries emptied. The Persian empire was no more, and the case of the Byzantine empire was dire. For the next two centuries, the Byzantine empire fought for its life, its survival doubtful.

The causes of the Arab Muslim success were only partly due to the weakness of its opponents. The Arab forces were infused with the élan and spirit of converts. God, they believed, was on their side, and as a result of their nearly immediate victories, their élan was rewarded with great wealth. After the first victories, a wave of enthusiasm swept the Arabian Peninsula, and recruits, lured on by the promise of Paradise in the next world and riches in this world, flocked to conquering armies. The tide of Islamic conquest seemed unstoppable, and in about eight decades the Arab armies, with their Muslim converts, conquered the most extensive empire known until then, spanning much of western Eurasia from the Atlantic coast of Hispania to beyond the Indus River in South Asia.

By the middle of the eighth century, the Arab Muslim tide had run its course. In 718 the Byzantine Navy, using Greek fire, defeated the second Arab siege of Constantinople. The Byzantine empire rallied and, in time, drove the Arab forces out of Anatolia, back to Antioch. In Europe, the Frankish Army stopped the Arab onslaught at the Battle of Tours (732), and in the Punjab, Hindu troops, using their bamboo and steel longbows, stopped the Arab advance. As early as the middle of the seventh century, the Arab movement south from Egypt had stopped, and a durable treaty, the Baqt, had established a durable peace on that frontier.

By the middle of the eighth century, the expansive force of the Arab Muslim empire had been spent, and frontiers that lasted nearly three centuries emerged in northern Spain, eastern

Anatolia, and along the frontier of Sind. The Muslim frontier with Nubia remained stable for nearly six centuries.

Nubia versus Muslim Egypt— A 600-Year Truce

Relations between the medieval Christian Nubian kingdoms and Muslim Egypt were unique. Unlike the situation between Dar al-Islam (the Muslim world) and its non-Muslim neighbors in other parts of the medieval world, where jihad and crusade were often the rule, interaction between these Muslim and Christian neighbors was comparatively peaceful for about six centuries.

The Nubian kingdoms emerged in the late fourth to early sixth centuries CE. They were located just south of Egypt in the valley of the Middle Nile, in the modern republic of Sudan.

Muslim Arab armies, fresh from their great victory over Emperor Heraclius's Byzantine army at the Battle of Yarmuk, invaded Egypt in 639. By 641 they had driven the Byzantines from Egypt, ending six centuries of Roman occupation. From that time to the present, Muslims would dominate Egypt. The northern Nubian kingdom, Makuria, had been a Byzantine ally, but because of the swiftness of the Muslim campaign the Nubians failed to come to the aid of their ally. Nevertheless, the Arab emir (governor) of Egypt, El As, sent an army, reputed to have numbered 20,000, to invade Makuria. The Muslim army rampaged through the land pillaging and killing, but a Nubian defense force, which the Muslims claimed was 100,000 strong, drove the invaders back into Egypt.

El As sent a second army into Makuria in 652. According to Muslim sources, this was in retaliation for a Nubian raid on Aswan, which the Egyptians had taken from Makuria in the previous combat. The Egyptian army, with 5,000

MUSLIM CONQUESTS, CIRCA 750

➤ A GIRAFFE FOR THE CALIPH—THE *BAQT*, A GIFT EXCHANGE AGREEMENT

The treaty, or *Baqt*, between the Muslim caliphate and the Nubian Makuria kept the peace, with a few exceptions, between the two powers for six centuries. Fundamentally it was a nonaggression pact, but it also provided for annual (later, triennial) gift giving between the parties. The Nubians were to give slaves to Egypt and its officials, while the Egyptians were to give the Nubians grain, wine, cloth, and two swift horses.

A tenth-century Egyptian account stipulated the schedule of gifts as follows:

From Makuria to Egypt and its officials:

Slaves—356 slaves to the Caliph, 40 to the governor (emir) of Egypt, 25 slaves to the officials supervising the gift exchange, and one slave each to the 12 witnesses for the gift exchange
Giraffes—an occasional giraffe for the Caliph

From the Caliphate to the Makurians:

Grain—1,000 measures of wheat and 1,000 measures of barley for the King and his treasury, 300 measures of wheat for the Makurian ambassadors
Wine—1,000 amphorae for the king, 300 for the Makurian ambassadors
Horses—2 swift horses from the emir's stables
Cloth—40 quantities of 6 kinds of cloth, 1 quantity of silk

In addition, the Egyptians were obligated to provide sustenance for certain Makurian embassies.

—Wilfred J. Bisson

horsemen, drove the Nubian defenders more than 300 miles south and laid siege to Dongola, the capital of Makuria. Although the Muslims used catapults, which they had brought up the Nile River on ships, the Makurian archers created such havoc among the besieging Muslims that they withdrew.

The strength of the Makurian army was its bowmen. These well-trained troops had the ability to shoot armor-penetrating iron and copper alloy-tipped arrows very rapidly from very powerful compound bows. The Muslim attackers

were astounded at the accuracy with which the Nubian archers could shoot their arrows. They complained that they could never get close enough to the Makurian soldiers to be able to use their swords.

As a result of this defeat, the Muslim commander agreed to a treaty, or *baqt*, with the Makurian king Qalidurut. This was an agreement that was to govern the relations between Egypt and Makuria for the next six centuries. It was a rare agreement for the Muslim caliphate at this time because it was an agreement among equals. It was more usual in early Muslim treaties for the non-Muslim party to be put in an inferior position. There was nothing in the terms of the *baqt* to imply a status of inferiority on the part of Makuria.

The *baqt* was a nonaggression treaty that acknowledged Makuria's independence and fixed the border just south of Aswan. It regulated commerce between the two powers, allowing traders from each country to operate in the territory of the other, but prohibited settlement. In addition, the *baqt* instituted a regular exchange of gifts between the two parties: Nubian slaves for the Muslims, and Egyptian grain, wine, horses, and cloth for the Makurians.

Until the thirteenth century, the *baqt* guaranteed peace of a sort between Egypt and Makuria. There were times when the Egyptians attacked Makuria, claiming that the Nubians were not fulfilling their agreement. At other times the Makurians raided into Egypt, pillaging Egyptian oases. In 748 the Makurian king Cyriacus went so far as to send an army deep into Egypt, even camping on the outskirts of Fustat, then the Muslim capital of Egypt. The provocation for Cyriacus's action was religious: the Muslim governor of Egypt had imprisoned the Coptic patriarch, who was revered by Nubian Christians. The Muslim governor then released the patriarch, and the Makurians went back to their homeland.

In the ninth century Muslim raiders, not controlled by the Egyptian government, began raiding the Beja, camel nomads who dwelt between the Nile and the Red Sea. One of these raiders, el-Omari, after capturing some of the Beja as slaves and converting the rest to Islam and developing a gold mine, attacked and occupied Makurian settlements. Eventually el-Omari

was driven out of Makurian territory, but not until after he triggered a civil war between the Makurian king's sons.

This Muslim incursion was the most serious until 1173, when the Makurian king took advantage of what he thought was a time of weakness and attacked the Muslim fortress of Aswan. The Muslim ruler, Salah ed-Din (Saladin), sent a punitive force south but had to withdraw it to face attacks by European crusaders in the north.

The *baqt* ceased to have much importance after the Muslim invasion of Makuria in 1265. The Muslims occupied Dongola, the Makurian capital, and forced Makuria to pay tribute. From then on Makuria existed as a tributary vassal of Muslim Egypt. Muslims began to buy land and settle on Makuria, and the Egyptian authorities frequently interfered with succession to the Makurian throne. By 1315 the kings of Makuria were Muslim, and the Islamification and Arabization of Nubia proceeded without hindrance. Within a few centuries the population had converted to Islam and adopted the Arabic language.

The life span of the Christian Nubian kingdoms was roughly contemporaneous with that of the Muslim Spanish states. Both the Muslim Spanish states and the Christian Nubian kingdoms existed for roughly 800 years. Both experienced periods of intensive warfare with neighbors of a different religion. The Muslims in Spain were finally defeated at the end of the fifteenth century, while Alwa, the southernmost Christian Nubian kingdom (about which little is known), might have persisted until the early sixteenth century. But for about six centuries there was relative peace between the Christian kingdoms and Muslim Egypt.

How the Muslims Simultaneously Defeated the Byzantines and the Persians

One of history's persistent questions is posed by the swift and nearly simultaneous defeat of two of Eurasia's strongest and most professionally trained armies by a horde of desert raiders who were inexperienced in sustained warfare. In retrospect, the Muslim's defeat of this pair of the world's mightiest empires is astonishing. But there are explanations.

The appearance of the unifying ideology of Islam coupled with the skillful use of both traditional and novel means of political consolidation resulted in the emergence under Muhammad and Abu Bakr of a new state that was able to organize and dominate more effectively than ever before the different tribal groups of the Arabian Peninsula. In place of the extreme political fragmentation that had formerly existed in Arabia, with various tribal groups vying with one another for local dominance, there emerged a relatively centralized, unified, and unifying polity that integrated most of these tribes into itself and made them functioning parts of the larger whole. Thus the Prophet Muhammad had made Medina, his adopted city, and Mecca, his birthplace, centers of an Arabian movement that Muslim Arabs developed into a world movement through the conquest of Persian and Byzantine territories.

It was this integration of the Arabian tribes into a single new Islamic state that set the stage for the conquests, which in fact represented the fruit of that integration. The process of state consolidation that began with Muhammad continued unabated throughout the whole period of the early Islamic conquests. This continuing process of state integration can be seen in the fact that tribal groups subject to the state were liable to the recruitment of their members into the Islamic armies sent to fight on various fronts during the conquests. These recruited tribesmen were not simply a horde wandering aimlessly toward the Fertile Crescent but instead were organized into contingents of a well-coordinated army whose objectives and general movements were established by the ruling elite.

Neither Sassanian Persia nor the Byzantine empire had been unfamiliar to those Arabs who

➤ KHALID—MUSLIM MILITARY GENIUS

Inspired military leadership can often make up for deficiencies in military traditions and troop numbers in military contests. Napoleon demonstrated that in early nineteenth-century Europe, and Vo Nguyen Giap did so in twentieth-century Vietnam. Khalid ibn Al-Waleed was the inspired military leader who led Islam's armies to defeat both the Romans and the Persians.

Khalid's accomplishment parallels those of Alexander the Great and Julius Caesar in significance and consequence because without Khalid's victories, Islam very likely would not have spread beyond Arabia, and Islam might have withered away.

It has been said of Khalid that he never was defeated in battle. His career as a successful military leader began when he led a Quraish force to defeat Mohammed's Muslim troops in the Battle of Uhud. Soon after the battle, Khalid submitted to Mohammed and became a devout Muslim. Khalid was elected general by Muslim troops after

Mohammed's three first appointees were slain in battle. The small Muslim army defeated a much larger force of Byzantines and their Arab allies. Next, Khalid led a Muslim expeditionary force that terrorized into submission rebellious Arab groups in the Wars of the Riddah. Five years after the Prophet's death, we find Khalid leading armies against the Sassanian empire, where they decisively defeated the Persians in the Battle of Qadisiya. But Khalid's greatest triumph was against the Byzantines when he destroyed a Byzantine army several times the size of his Arab forces at the Battle of Yarmuk in Palestine. By these two victories, he drove the Persians from Iraq and the Byzantines from Palestine and Syria.

After his victory at Yarmuk, Caliph Umar relieved Khalid of his command purportedly because of jealousy over Khalid's rising popularity, but Khalid refused to retire to Medina and served the rest of his life as a common soldier.

—Wilfred J. Bisson

were the former's Lakhmid and the latter's Ghasanid vassals, the frontier guardians of the two empires against fellow Arabs who roamed deeper in the Arabian Desert. Also, Meccan and Medinese Arabs had established commercial connections with the Byzantines and the Sassanians. The immunity of Mecca's ancient sanctuary, the Kabah, against outlawry and outrage had promoted this city's commercial importance. The Kabah was cleansed of idols by Muhammad, who had himself once been engaged in commerce. He made it the sanctuary of a monotheistic faith whose sacred writings were filled with the injunctions and prohibitions needed by a business community for secure and stable trading.

Arab tribalism beyond urban fringes was less easily broken than idols. It was embedded in the desert sparsity that led to warfare and carefully counting a tribe's male offspring. After Mecca and Medina had become Muslim, it was essential that the Muslims win the desert Arab's allegiance in order to secure the routes they depended on for trade and communication. In the process of doing this, wars over water holes, scanty pastures, men-at-arms, and camels were enlarged into international campaigns of expansion.

The vulnerability of Sassanian Persia assisted the expansionist process. In 623 the Byzantine emperor Heraclius reversed Persian successes over Roman arms, namely by capturing Jerusalem in 614 and winning at Chalcedon in 617. His opponent, Khosrow Parviz, died in 628 and left Persia prey to a succession of puppet rulers who were frequently deposed by a combination of nobles and Zoroastrian clergy. Thus when Yazdegerd III, Persia's last Sassanid emperor, came to the throne in 632, the year of Muhammad's death, he inherited an empire weakened by Byzantine wars and internal dissension.

The war between Persia and the Byzantine empire had created the perfect opportunity for the Muslims to invade and surprise both of them. Neither the Persian empire nor the Byzantine empire had enough strength to repulse the Muslim attacks. It did not take long for the Muslims to conquer the eastern province of the Byzantine empire. Not only was the empire weakened by the war with Persia, but it was also weakened by internal division due to a desire to maintain orthodox Christianity within the empire. Many Christians wanted to keep the empire pure and looked upon certain religious sects as heretics.

Monophysites, who believed that Christ had a single nature, not two as orthodoxy taught, were especially persecuted. To these people, life under Islam was more appealing than life under Byzantium because Muslims tolerated other religions, and those incorporated into the Muslim empire were free to practice what religion they chose. Many Byzantine dissenters, therefore, welcomed the Muslim conquerors.

To these factors must be added one more that was perhaps the single most important one contributing to the success of the conquests: the remarkable degree to which a new Islamic state with an expansionist policy could harness for its purposes the warriors and tribesmen of Arabia. The rise of the state made it possible to weld into an incredibly effective fighting force those tribesmen, whom the Byzantines and the Sassanid knew, whose energies had hitherto been consumed by petty quarrels among themselves and whose political horizons had hitherto usually been limited to their own tribe and its affairs.

Muslim Conquest of the Maghreb

After completing the conquest of Egypt in 642, the Arabs started to raid the territory to its west inhabited by the Berbers, which they called Bilad al-Maghreb (Lands of Sunset), or simply the Maghreb. In 705 this region became a province of the Muslim empire, then ruled from Damascus by the Umayyad caliphs.

The Byzantine (East Roman) empire ruled the Maghreb as an exarchate (vicerealty, or sub-kingdom) in much of the seventh century. Because of a disagreement over religious policy with Byzantine emperor Constans II (r. 641–668), Gregory, exarch (viceroys or governor-general) of

➤ KAHINA—BERBER PROPHETESS AND AFRICAN QUEEN

The Muslim conquest of the Maghreb was stoutly resisted by the Berbers and required two decades and repeated invasions by Muslim forces. Dhabba, sometimes known as the Berber Deborah, the chieftainess of a Berber tribe in the Aures Mountains, was one of the Muslim's fiercest opponents. Leading a Berber army, she defeated the Muslims in 698 and captured Carthage, the leading city of the Maghreb. The Muslims retreated to Egypt, and Dhabba, called Kahina (Prophetess), became the queen of a large swath of the Maghreb. According to some reports, she told her followers that what lured the Muslims to the Maghreb was the wealth of the land and urged them to destroy the cities and farms so that the Muslims would not be tempted to return. This was a disastrous mistake because it turned the sedentary population against her and her nomadic followers. When in 702 the Muslims did return, the inhabitants of the destroyed towns and villages made common cause with them. The Muslims easily defeated Kahina's forces, and Kahina died, reputedly by her own hand. But before the final battle, Kahina sent her two sons to the Muslims with instructions to convert to Islam so that her family would not be destroyed.

the Byzantine exarchate of Carthage, rebelled (647) and ruled as an independent sovereign. The dominions of Gregory extended from the borders of Egypt to Morocco.

Arab raids to the west of Egypt concentrated at first on the area of Cyrenaica in present-day Libya, which they conquered in 642. They raided Ifryqia (Tunisia) several times. Gregory attempted to halt the Muslim advance but met defeat and death at the Battle of Sufetula in 647. After Gregory's death, the Byzantines reasserted their rule, appointing a new exarch, Gennadius. Gennadius sought to avoid a Muslim takeover by offering tribute to the Muslim authorities at Damascus

while simultaneously paying taxes to Constantinople. The burden was too great, and the population, particularly the Berbers, rebelled.

However, no attempt was made to establish Arab rule in the exarchate before 670. Conflicts among the Muslim leaders, especially after the assassination of the third caliph Uthman in 656, hindered Muslim territorial expansion. Only after the Umayyads had consolidated their authority in the 660s and had come to view the conquest of the Maghreb in the context of their confrontation with the Byzantine empire was the systematic conquest of the Maghreb undertaken. Uqbah ibn Nafi commanded the Arab army that occupied Ifryqia (the Arab term for the exarchate) in 670. Before his recall in 674, Uqbah founded the town of al-Qayrawan (Kairouan), which became the base for further military operations and also the first center of Arab administration in the Maghreb.

When Uqbah's successor Abu al-Muhajir Dinar al-Ansari began the conquest of the Maghreb west of Ifryqia, he had to fight seminomadic Berber communities that had developed some tradition of centralized political authority. In the course of his campaign, Abu al-Muhajir Dinar prevailed upon the Berber king Kusaylah to become Muslim. From his base in Tlemecen, Kusaylah dominated a confederation of the Awraba tribes living between the western Aures Mountains and the area of present-day Fez. Since Kusaylah's profession of Islam implied his recognition of caliphal authority, it served as a basis for coexistence between him and the Arabs. However, when Uqbah was reinstated as commander of the Arab army in the Maghreb in 681, he insisted on imposing direct Arab rule over the whole region. In 682 he led his troops across Algeria and northern Morocco, reaching the Atlantic Ocean and penetrating south to the area of Sous in southern Morocco. On his way back to al-Qayrawan, Uqbah was attacked near Biskara in present-day Algeria on orders from Qusaylah by Berbers supported by Byzantine contingents. Through his death in this battle and his extended campaign, Uqbah became the legendary hero of the Muslim conquest of the Maghreb.

By the 680s the Arabs had gone too far in the conquest of the Maghreb to be willing to accept defeat at the hands of a Berber leader, albeit

one professing Islam. Two large armies had to be sent from Egypt, however, before organized Berber resistance could be suppressed. The first, commanded by Zuhayr ibn Qays al-Balawi, reoccupied al-Qayrawan and then pursued Qusaylah westward to Mams, where Qusaylah was defeated and killed. The dates of these operations are uncertain, but they must have occurred before 688 when Zuhayr ibn Qays himself was killed in an attack on Byzantine positions in Cyrenaica.

The second Arab army, commanded by Hasan ibn an-Numan, was dispatched from Egypt in 693. It faced stiff resistance in the eastern Aures Mountains from the Jawara Berbers, who were commanded by a woman whom the Arabs referred to as Kahinah (al-Kahinah, or the Priestess). After Kahinah was defeated in 698, Ibn an-Numan occupied Carthage, the center of Byzantine administration in Tunisia, and began the construction of the town of Tunis nearby.

These successes and Arab naval supremacy in the Mediterranean forced the Byzantines to evacuate their remaining positions on the Maghrebi coast. Consequently, under Ibn an-Numan's successor Musa ibn Nusayr, the Maghreb was made into a province of the Umayyad caliphate in 705, known as Ifriqiya, thus separating it from Egypt to which it had been administratively attached until that time.

Muslim Conquest of Spain

The year 711 was one of triumph for the Umayyad caliphate when Muslim armies conquered both the Indian kingdom of Sind and Visigothic Spain, more than 5,000 miles to the

west. In that year, a Berber army under Arab leadership crossed the Strait of Gibraltar from Africa in a continuation of a series of raids that had been going on for some time. After a single campaign, almost the entire peninsula lay at their feet. The early-eighth-century conquest signaled the beginnings of an Islamic presence in the Iberian Peninsula that would endure for nearly 800 years and serve as a leading center of Islamic culture.

In the early years of the eighth century, a succession struggle, which Roderic won in 711, convulsed the Visigothic court of Spain. Taking advantage of that crisis, Musa Ibn Nusair, governor of the Maghreb, sent Tariq ibn Zayid with an army of 7,000 to invade Spain. Tariq's army crossed the Strait of Gibraltar ("Tariq's Rock") on ships provided by Julian, a Christian who was on the losing side of the Visigothic succession struggle. In the Battle of Guadalete, Tariq, assisted by Julian's troops, decisively defeated and killed Roderic, leaving all Spain open for conquest.

Musa followed shortly afterward with an army of 18,000. Proceeding to Toledo, he executed a number of prominent people and devastated the country. The archbishop of Toledo, primate at the Spanish church, abandoned his flock and fled. Musa then moved north to the valley of the Ebro River, where he took the principal city of the region, Zaragoza.

Before the end of 712 Musa left Spain, recalled by the Umayyad caliph to Damascus. Musa took with him a number of lordly Visigothic captives (including a claimed 16,000 Visigothic virgins) and huge quantities of booty in the form of bullion and jewelry. Musa's death is variously reported. He may have been executed by the enraged brother of the caliph, he may have died on a pilgrimage to Mecca, or perhaps, as another account maintains, he died as an impoverished beggar in Damascus.

Before he left, Musa entrusted the administration of the conquered provinces to his son, Abd al-Aziz, who spent the three years of his governorship (712–715) extending and consolidating his father's conquests until they embraced the whole of the Iberian Peninsula except for a small region north of the mountains in Asturias. In 715 or perhaps a few years later Abd al Aziz was assassinated in a mosque, reput-

➤ BATTLE OF TOURS

The Battle of Tours (often called the Battle of Poitiers) was fought on October 25, 732, between forces under the Frankish leader Charles Martel and an Islamic army led by Emir Abd er Rahman. During the battle, the Franks defeated the Islamic army, and Abd er Rahman was killed. The result of this battle stopped the northward advance of Islam from Spain. This battle is considered by most historians to be of macrohistorical importance in that it may have halted the invasion of Europe by Muslims and preserved Christianity as the controlling faith during a period in which Islam was overrunning the remains of the old Roman and Persian empires.

—Moshe Terdiman

edly on the order of the caliph. The report is that the caliph had Abd al Aziz's head sent back to Damascus, where it was displayed in a mosque.

In the northern mountains of Astoria, Pelayo, a claimant of the Visigothic throne, continued a guerrilla resistance that the Muslims never suppressed and that, in the centuries to come, became the foundation of the Spanish Christian kingdoms.

Muslim forces did not stop with the conquest of most of the Iberian Peninsula, sending probing and raiding expeditions north of the Pyrenees. In 723, a major Muslim force was defeated by Odo, Duke of Aquitaine, at the Battle of Toulouse in southern France. Muslim advances in western Europe were effectively stopped (732) when the Arab emir of Al Andalus, Abd er Rahman, was decisively defeated at the Battle of Tours (Poitiers) by a Frankish army led by Charles Martel (the Hammer).

Muslim Conquest of Iran and Central Asia

In 600 Mesopotamia was a province of the Persian Sassanian empire to which it had belonged for three centuries. It was probably the most populous and wealthy area in the Middle East, and the intensive agriculture of the lower Tigris and Euphrates rivers and of tributary streams, such as the Diyala and Karun, formed the main resource base of the Sassanian monarchy.

The first conflict between Muslim troops and Sassanian forces seems to have been in 634, when the Arabs were defeated at the Battle of the Bridge

► PIROOZ AND THE ROYAL SASSANIAN COURT IN EXILE

After the Muslims crushed Persian resistance in 650 CE, Yazdgerd III, the last Sassanian king, fled with the royal family and many nobles to what is today Turkmenistan. The pursuing Arabs captured Yazdgerd and beheaded him (by another account, a miller robbed and murdered the fugitive Yazdgerd), but many of the fugitives escaped. Fleeing through central Asia and across the Pamir Mountains, these aristocratic refugees, who included Persians, Sogdians, and Bactrians, sought asylum with the Tang dynasty in China.

Pirooz, though still a child, was Yazdgerd's son and heir, while Yazdgerd's daughter was one of the wives of the Tang emperor. The Tang emperor aided the exiles, reputedly giving them 38 villages and allowing them to set up a royal court in exile. The Chinese trained Pirooz in military arts and, when he had reached maturity, gave him a general's rank in the Chinese army. However, the Chinese for many years would not allow Pirooz to serve with their forces guarding the western frontier for fear that he would attack Muslim-controlled territory. Eventually, Pirooz did win an appointment to a command on the western frontier. The consequence of that was an outbreak of hostilities with the Arab Umayyad caliphate. These hostilities continued intermittently until the decisive defeat of Tang armies at the Battle of Talas in 751.

Pirooz died in 700 CE and was buried with an elaborate ceremony attended by all the Sassanian court-in exile.

—Wilfred J. Bisson

on the banks of the Euphrates River. There, a force of some 5,000 Muslims under Abu Ubayd al-Thaqafi was routed by the Persians. In 637, a much larger Muslim force under Saad ibn Abi Waqqas defeated the main Persian Army at the Battle of al-Qadisiyyah in southern Mesopotamia and moved on to sack Ctesiphon, the capital of the Sassanian empire. By the end of 638, the Muslims had conquered almost all of Iraq, and the last Sassanian king, Yazdgerd III, had fled to Iran.

In 642, the Battle of Nahavand (in western Iran) between Arab and Sassanian forces was a major turning point in Iranian history. The battle ended in disastrous defeat for the Sassanian armies and paved the way for the Arab conquest, which resulted in the Islamization of Iran. At Nahavand some 30,000 Arab troops, under the command of Numan, attacked a Sassanian army alleged to number 150,000 men, many of whom may have been untrained recruits. The Sassanian troops, commanded by Firuzan, were entrenched in a strong fortified position. After an indecisive skirmish, Numan pretended to be defeated and withdrew from the battlefield. Firuzan then abandoned his position and pursued his foe. This pursuit proved to be a major tactical error because the Sassanians were forced to fight on unfavorable ground: the Sassanian Army, caught between two mountain defiles, was massacred by the Arabs. Both Numan and Firuzan died in the battle, and Sassanian casualties were said to number 100,000.

The Battle of Nahavand completed the Sassanids' defeat. Yazdgerd fled to the empire's northwestern outpost, Merv, whose governor, Mahuyeh, was soured by Yazdgerd's imperious and expensive demands. Mahuyeh turned against his emperor and defeated him with the help of Hephthalites from Badghis (today in northwestern Afghanistan). The Hephthalites, originally a nomadic people from central Asia, had troubled the Sassanians since at least 590. A miller near Merv is reputed to have murdered Yazdgerd for his purse. Another account has the Arab commander capturing and ordering the execution of the erstwhile Sassanian ruler. With the death of Yazdgerd III in 651, the Arab conquest of Iran was completed.

In 651, Merv surrendered before the Arabs, and it became their base for raids to Mover-

rankhr, the territory of modern Uzbekistan. Around 670 or earlier, the Arab commander Al-Khakim Amr Al-Gifari was the first to cross the Amu Darya River.

More actively, the Arabs began their invasion into central Asia during the reign of the governor-general of Khorasan, Ubaidallah bin Ziyad, in 674. He besieged Pykend and conquered Bukhara, seizing its princess, arms, clothing, gold, silver, and numerous captives. The rulers of Soghd, Kesh, and Nesev came to the aid of Bukhara, but the Arab army had them so panicked that they left the battlefield.

In 704 Qutayba bin Muslim was appointed governor-general of Khorasan, and he set as his objective the conquering of Mawaranahr, or Transoxiana, the right side of the Amu Darya River. In 705–706, he subjugated Balkh, Pykend. However, he faced a fierce resistance of Sogdians and Turks led by the head of Bagdis, Nizal Tarkhan, who forced him to retreat. In 709, Qutayba took over. Tarkhan was destroyed and murdered, and Bukhara surrendered without much effort. Soon Qutayba conquered Shoumen, Nesev, and Kesh. Everything was ready for the Arabs to advance to the heart of Sogd, Samarqand; however, some affairs in Khorezm distracted Qutayba for almost two years.

In 712, Qutayba launched a raid to Samarqand and faced fierce resistance by Gurek, governor of Samarqand. The Arab army was using spears and wall-piercing weapons. After a long fight, Qutayba took over the city. Qutayba collected a huge tribute from Samarqand.

Qutayba proceeded to march east and conquered Khudjant and Fergana, but in Shash he encountered the resistance of its ruler, Turk Bahadur-Tudun. In 715 Qutayba, having heard about the death of the reigning caliph, initiated a revolt but was killed in Fergana by his troops.

In the middle of the eighth century, the entire territory of Mawaranahr (Transoxania) surrendered to the Arabs and became part of the Abbasid caliphate. A key event was the Battle of Talas River in 751 in the High Pamirs. The battle was a conflict between the Abbasid caliphate and the Chinese Tang dynasty over the control of central Asia. The Arab cavalry routed the Chinese infantry near the bank of the Talas River after the Qarluq Turk mercenaries, who had

marched with the Chinese, defected to the Arabs and cut off the infantry from the rest of the Chinese troops. The Tang Chinese army of 30,000, led by General Gao Xianzhi (a Korean), was defeated, but their commander escaped.

Due to this defeat and the domestic rebellion of An Lushan and subsequent warlordism, the Tang ceased to be influential in central Asia. The local Tang tributaries then switched to the authority of the Abbasids, and the introduction of Islam was thus facilitated among the Turkic peoples. In the long run, the battle is significant because it marked the western limit of Chinese cultural and political influence, thereby determining that central Asia would be more influenced by Islamic culture than by Chinese culture. The technology of papermaking also spread to central Asia and the Middle East, as the skilled Chinese prisoners of war were ordered to produce paper in Samarqand. The Arabs halted their push after a defeat at the hands of the Khazars in Azerbaijan.

Wars between Muslims and the Byzantine Empire to 1000 CE

The early years of the seventh century saw the replacement of the ancient struggle for supremacy in the Near East between Byzantium and Persia by a new contender. The endemic warfare between the Byzantines and the Muslims that followed was to last for over eight centuries.

During the course of the first Islamic century (622–722 CE), Arabs overran the Fertile Crescent, detaching Syria and Egypt from the Byzantine empire. They also conquered North Africa as far

west as Morocco, finally putting an end to Byzantine dreams of restoring their hegemony in the western Mediterranean beyond Sicily.

The momentum of Muslim conquest was at its strongest during the period of the Orthodox caliphs (632–661) and that of the Umayyad caliphs (661–750). Although the Arabs were strangers to Mediterranean seafaring, they had now acquired the naval resources of Syria and above all Egypt with the services of their maritime populations. Using these, the Arabs raided Cyprus as early as 649, Rhodes in 654 and 672, and Crete in 674, and they defeated Emperor Constans II in person with his fleet at Phoenix off the Lycian coast in the Battle of the Masts in 655. The Muslim fleet under the command of Busr ibnabi Artah, in cooperation with the Egyptian fleet under Abdullah ibn-abi Sarh, defeated the Byzantine fleet by transforming the sea fight into a hand-to-hand encounter by tying each Arab ship to a Byzantine vessel. This defeat was a catastrophe for the Byzantines, but the Muslims failed to follow up this naval victory, probably because of the murder of the caliph Uthmar, which occurred about this time, and other concomitant civil disturbances.

The Muslims first besieged Byzantium itself in 669 under the leadership of Caliph Muawiya's son Yazid, the future Caliph Yazid I. The second attack on Constantinople was made during the Seven Years' War of 674–680, which was waged mainly between the two fleets before Constantinople. The Muslims had secured a naval base in the Sea of Marmara on the peninsula of Cyzicus. This served as winter headquarters for the invading army, and hostilities were resumed every spring. The use of Greek fire is supposed to have saved the city. On the death of Muawiya in 680 the Muslim fleet withdrew from the Bosphorus and Aegean waters. However, the supreme Muslim effort was made in August 716–September 717 by the caliph Sulayman, who designated his half-brother Maslama b. Abd al-Malik to be supreme commander of the attacking forces. These comprised the Syrian army by land and the Egyptian fleet by sea. Maslama's investing forces suffered terribly from the unusually cold winter of 717 and the lack of provisions in Thrace, normally a fertile province but one now devastated by war. When the new caliph Umar II came to

the throne in 717, he abandoned the expansionist policy of his predecessors, turning his attention to the urgent internal tasks of social and financial reform within the Islamic empire. Hence, he immediately gave orders for Maslama to abandon the siege of Constantinople.

This was the last direct Muslim effort against Constantinople for over seven centuries, although an army under the nominal leadership of the young prince Harun, later the caliph Harun al-Rashid, was to appear at Scutari in 781–782 before Empress Irene bought the Muslims off by a timely offer of tribute.

After the debacle of 717, Muslim-Byzantine warfare declined for a century and a half (until the Macedonian resurgence) to episodic warfare and raiding. The Muslims dispatched raiding parties or armies into Anatolia each spring and summer, and their highly mobile cavalrymen often penetrated right across the Anatolian plateau nearly to the Aegean Sea.

In the second half of the ninth century, the Muslims occupied the strategically important island of Malta, and in the year 878, Muslims from the Aghlabid emirate of Ifryqia occupied Syracuse after a siege of nine months. After the loss of Syracuse, the Byzantine empire retained only the city of Tauromemium, or Taormina, on the eastern coast of the island. Later, the Muslims occupied the city of Rhegium (Reggio) on the Italian shore of the Strait of Messina, and thus the strait was completely in the hands of the Muslims. In 902 they completed the conquest of Sicily with the seizure of Taormina.

The beginning of the tenth century was marked by active operations of the Muslim fleet. Even at the end of the ninth century Cretan pirates had repeatedly raided the coasts of the Peloponnesus and the islands of the Aegean Sea. These sea raids of the Muslims became more dangerous when their Syrian and Cretan fleets began to act together. The attack of Thessalonica by the Muslim fleet under the leadership of the Greek renegade Leo of Tripolis in 904 is the most famous deed of the Muslims in this period. The city was taken only after a long and difficult siege, but a few days after its fall the conquerors departed with a large number of prisoners and rich spoils, setting sail eastward to Syria. In 906 the Byzantine admiral Himerius gained a bril-

liant victory over the Muslims in the Aegean. But in 911 the great sea expedition of Emperor Leo VI against the eastern and Cretan fleet, also headed by Himerius, ended in complete failure for the empire. However, in 917 Leo of Tripolis was defeated at Lemnos.

By the mid-tenth century, the Byzantines switched from the defensive to the offensive. During the brief reign of Romanus II (959–963), his general, Nicephorus Phocas, the future emperor, reoccupied the island of Crete.

In 962 the future emperor Nicephorus Phocas (963–969) invaded northern Syria, and in 966 he laid waste to the Syrian Jezira. Again in 968 he entered Syria, capturing and sacking Shaizar, Hama, and Homs. From Homs the emperor descended to the coast of Lebanon, which he laid waste to on his return march to Tarsus. Meanwhile, Cyprus had been reconquered from the Muslims, and the Byzantine fleet had gained command of the sea. On October 29, 969, the Byzantines seized Antioch. In 975 John Tzimiskes (969–976) conquered Syria and from there continued to Tiberias, which surrendered without resistance. He made forays into Palestine, but since the Byzantines had not enough men to garrison them, most of his conquests were immediately reoccupied by the Muslims. The area that remained under Byzantine control was a strip of coastline extending from Tortosa to Alexandretta with a slight extension inland east of Antioch.

Basil II (976–1025) marched in 995 with 40,000 men from the Balkans to Antioch. He pressed on into Syria, occupied Shaizar and Homs, and visited Tortosa but failed to take Tripoli. Then, in 999, he repeated the same campaign, reaching a point a little north of Baalbek and arriving back in Antioch in January 1000. Neither campaign made any permanent change in the frontier, for the emperor had not enough men to garrison the places he captured.

The Caliph's Armies, 632–1000 CE

The military organization of the Islamic armies went through a transformation in the period between the death of Muhammad in 632 and the turn of the first millennium of the Common Era. The armies inherited by Muhammad's uncle and successor, Abu Bakr, the first of the four "Rightly Guided Caliphs" (632–661 CE), consisted of Bedouin Muslims recruited from the faithful in the Arabian Peninsula. These first troops were well armed with long iron swords, javelins, and bows and were protected by felt armor and small round leather shields. Abu Bakr's forces fought in close formation, mirroring the infantry tactics of the seventh-century Byzantine army, and used archers as skirmishers and to protect their flanks from enemy cavalry attacks. Although initially poorly equipped with horses, Islamic cavalry improved when Yemeni Najran and Yamamah came under Muslim control, providing the caliph's army with highly prized Arabian and heavier Persian horses. In battle, Islamic cavalry utilized light lances and would harass the flanks of enemy infantry formations and exploit any tears or breaks in the ranks. Early Muslim armies also made good strategic use of the camel for mounted infantry, bypassing enemy armies by traveling through deserts and then dismounting and fighting defensive battles at the time and place of their own choosing.

As Islamic conquests expanded into North Africa and the Levant at the expense of the Byzantines and Sassanids, manpower requirements necessitated organizing the newly conquered and converted peoples into *junds*, or regional armies, under the direction of Arab commanders. These troops fought more for booty than ideology, swelling the ranks of the Muslim armies in time of victory and evaporating in times of trouble. Junds were often used to garrison cities but also formed the backbone of Muslim armies that spread Islam from Persia to the Straits of Gibraltar. In fact, the Arab commander who crossed from North Africa to Iberia in 711,

► ISLAMIC FORTIFICATION AND SIEGECRAFT

Siege warfare was not an important part of early Islamic military activity. When enemy fortifications were faced, negotiations or blockade rather than assaults usually determined the outcome. When a city wall was attacked, Muslim commanders used a type of counterweight artillery piece called a *manjaniq*, similar to the European trebuchet, replacing the classical torsion machines favored in the Classical Period. Islamic siegecraft did develop over the course of the Umayyad and Abbasid caliphates, as Muslim commanders were faced with more determined non-Muslim foes behind stronger walls. Perhaps the most famous of these unsuccessful sieges took place against the Byzantine capital of Constantinople in 674–678 and again in 717–718.

It was during this first siege that the Muslim attackers were introduced to Greek fire (a burning-liquid weapon), when the Byzantine navy set the Umayyad flotilla ablaze at the Battle of Syllaeum in 677. Purportedly invented by the Syrian engineer Callinicus in the chemistry laboratories of Constantinople, this liquid fire was hurled onto enemy ships through siphons, burst into flames on contact, and could not be extinguished using water. Although its exact composition remains a mystery, its recipe was handed down from Byzantine emperor to emperor for centuries and probably included some combination of chemicals including liquid petroleum, naphtha, burning pitch, sulfur, resin, quicklime, and bitumen. Eventually, Islamic commanders would obtain the recipe for Greek fire and other incendiary devices and create specialized troops called *naффatin* (after *naффt*, which was most likely crude oil ubiquitous in this region) to employ these fiery weapons. Muslim siegecraft would be tested again during the crusades when the Catholic invaders introduced an ambitious castle-building program to the Levant.

—Brian Todd Carey

Tariq ibn-Ziyad, led a force of 12,000 Berber infantry, supported by only 300 Arab cavalry. Not all the junds came from conquered peoples. Some of the best soldiers from this period defected from the Sassanid army to the caliphs in exchange for high salaries and lands for settlement.

Under the Umayyad caliphate (661–750), Islamic armies began to mirror their enemies in tactics, equipment, and organization. The last Umayyad caliph, Marwan II (r. 744–750), is credited with standardizing his army, subdividing his forces into smaller units (*kardus*), each including heavy infantry, light infantry archers, and heavy cavalry lancers. Muslim infantry fought in the Byzantine fashion, placing the better-armored foot soldiers in the front. But unlike Byzantine horsemen, Islamic cavalry would dismount and fight as infantry, using their lances as pikes. Muslim heavy cavalry mounts were protected with felt barding, while their riders wore coifs and hauberks and were armed with mace, straight-hilted swords, and the large *khanjar*, or dagger. In order to better stabilize these heavier warriors on their mounts, the leather loop stirrup was replaced by metal ones.

These martial trends continued into the Abbasid caliphate (750–1258), though persisting contacts with central Asians began to impact the Islamic way of mounted war. Abbasid generals increasingly utilized Khurasani (eastern Persian) and Turkish horse archers, armored in lamellar cuirasses and round leather shields and armed with lance and bow. The composite Turkish bow was a recurved bow constructed of wood and horn and tendons from oxen, carefully laminated together to create a bow of superior strength, range, and impact power. It is also during this time that the Turkish warriors introduced the distinctive curved cavalry sword or saber, which was worn off the shoulder hanging from a baldric in the Roman fashion. Turkish influences continued to grow in the ninth century CE as junds were augmented by *ghulams*, or Turkish regular troops. Later, some of these ghulams, purchased as slave children and then trained and converted to Islam, would serve the Abbasid caliphs as their personal bodyguards. And like the Roman Praetorian Guard before them, these slave-soldiers were seldom employed against Islam's external enemies, becoming instead caliph-makers and architects of palace intrigue. Ghulam heavy cavalry was the finest in the Islamic world, marrying elements of steppe warfare (use of bow and lasso from horseback) with those of traditional mounted Islamic warfare (use of Arab lance and sword), fusing heavy and light cavalry into one.

Islamic infantry under the Umayyad and early Abbasid caliphates often fought using indigenous weapons and armor and according to regional tactics. The first North African infantry were poorly equipped with large leather shields and javelins, and if swords were carried, they were of poor quality. These men fought as free warriors, but later Islamic North African dynasties (most notably the Tulunids and Fatimids of Egypt) would utilize slave-warriors taken from Saharan tribes. In the Islamic east, Umayyad and Abbasid caliphs relied heavily on the Daylamis, a fierce people from the Elburz Mountains south of the Caspian Sea. Daylami warriors fought as heavy infantry behind shield walls, advancing slowly and using javelins to break up enemy formations before engaging with battle-axes and maces. The Khurasan region also provided Muslim commanders with excellent professional soldiers well versed in combined-arms tactics and, equally important, siegecraft.

Although the Abbasid caliphs would continue to be the symbolic leaders of Islam until the Mongol destruction of Baghdad in 1258 CE, by the ninth century the centralized empire enjoyed by earlier caliphs was replaced by political fragmentation. At the turn of the millennium, Turkish influence on Islamic warfare would increase dramatically with the appearance of the Seljuk Turks, who converted to Sunni Islam and overran Afghanistan and eastern Persia in the 1040s and entered Baghdad in 1055, becoming the de facto rulers of Abbasid holdings. The Seljuk empire reached its zenith in the 1070s with the defeat of the Byzantine emperor Romanus IV at Manzikert in 1071, robbing the eastern Roman empire of its prime Anatolian lands and precipitating the First Crusade. By the year 1000 CE, Islamic warfare was no longer controlled by the Arabic successors of Muhammad but instead was now the enterprise of the various converted peoples led by their commanders and political leaders.

The Early Muslim Civil Wars

During the early years of Islam, its followers were united religiously and politically to an extent that no other empire could claim. Muhammad's failure to establish a system by which successors could be named, however, led eventually to divisions and civil wars among the Muslims. Perhaps the most significant division revolved around whether the Prophet's son-in-law Ali was Muhammad's rightful heir. The dispute from 657 to 661 divided Islam religiously between Shias and Sunnis, a schism that has lasted to the present. A second civil war followed a generation later. Although its long-term effects were more limited, it marked the end of Medina and Mecca as administrative centers of Islam. Another civil war between 747 and 750 permanently divided Muslim territories politically, with separate states ruled by the Umayyad and Abbasid families.

Muhammad's death in 632 caused prominent Muslim leaders to elect his father-in-law, Abu Bakr, as the first caliph. Abu Bakr was succeeded by two other caliphs over the next 24 years. In 656, Caliph Othman was murdered after some Muslims rose up against his rule. They accused him of behaving secularly and not according to the spirit of Islam. He was also a member of the Umayyad family, which had opposed Muhammad in Mecca. Ali, cousin, son-in-law, and adopted son of Muhammad, was named by some leading Muslims as caliph, but many Muslims believed that he had some responsibility for Othman's death or at least that he refused to bring Othman's murderers to justice. Rebels led by Ayesah, widow of Muhammad, seized Basra soon afterward. Ali defeated them in what became known as the Battle of the Camel but could not put down the revolt. The resulting civil war became known as the First Fitna.

Muawiya, cousin of Othman and governor of Syria, refused to accept Ali as caliph. In response, Ali invaded Syria in 657. The two armies

➤ THEY KILLED FOR RIGHTEOUSNESS— THE ORIGIN OF THE KHARIJITES

The original Muslim fundamentalists, the Kharijites, demanded that the leaders of the ummah (Islamic community) be righteous in their behavior and adhere to a rigid form of conduct. They believed that political rule and behavior should follow demanding religious standards and that rulers who violated Muhammad's teachings should be removed. The Muslims who assassinated Othman could be considered the first Kharijites, but the group had its real beginnings in Ali's army. A number of men felt that Ali had compromised his piety and religious zeal by attempting to negotiate with Muawiya and withdrew from the army. They claimed that no political and administrative decisions should be made unless they followed the principles laid out in the Quran. Another guiding principle of the Kharijites was that grave sinners should be excluded from the larger community. Such exclusion meant a loss of rights, and extremists saw it as a moral justification for the assassination of leaders who did not follow Islam's teachings.

Ali attempted to reconcile the Kharijites to his cause, especially after Muawiya was named caliph. While many rejoined him, others refused. Ali's army massacred around 4,000 Kharijites at Nahrawan. In revenge, a Kharijite assassinated Ali in 660, using a poisoned sword.

—*Timothy J. Watts*

confronted each other, but peace negotiations dragged on for 110 days. Both sides were hesitant to kill fellow Muslims. Finally, a bloody and indecisive three-day battle took place. To halt the bloodshed, Muawiya proposed that an arbitration take place to decide who should be caliph. Ali reluctantly agreed. Part of his army accused Ali of betraying Islam's principles and withdrew. They later became known as Kharijites (dissenters).

Arbitration favored Muawiya, who was proclaimed caliph in Jerusalem in 660. Ali was murdered soon afterward by a Kharijite. His son renounced his claim as caliph the following year. While Muawiya governed politically, followers of Ali accepted his successors as the true spiritual leaders of Islam. These successors took the title of imam, or spiritual leader. The second imam

ceded the caliphate to the Umayyad family, thus formalizing the split between Sunnis and Shias.

A second civil war, or *fitna*, followed within 20 years. Ali's son, Hussain, revolted in 680 and was murdered after being defeated at the Battle of Karbala. Additional uprisings were put down by Umayyad caliphs in Iraq and Arabia before peace was restored in 692.

The civil war that ended the political unity of Islam took place from 747 to 750. Although Islam expanded to its greatest extent under the Umayyad caliphs, many Muslims believed that their rulers had become corrupted by secular success. Cultural achievements in literature, art, and architecture helped fuel the sense that they were too devoted to the secular. A series of weak caliphs after 743 helped bring a time of regional revolts and religious disputes. In 747, supporters of the Al-Abbas family rose in revolt. Al-Abbas had been a cousin of Muhammad and a close companion during Islam's founding. A series of victories in Khorasan caused uprisings in Persia and Mesopotamia. In 749, Al-Abbas's grandson Abul Abbas proclaimed himself caliph. The Umayyad caliph, Marwan II, was defeated at the Battle of the Greater Zab in January 750 and killed. Most of the Umayyad family was then systematically murdered. Even so, revolts in support of the Umayyad family took place in Syria and Mesopotamia between 750 and 754.

When Abul Abbas died in 754, his brother Al-Mansur proclaimed himself caliph. Other members of the Abbasid family objected and rose up against him. Al-Mansur spent the early years of his reign putting down revolts, including an uprising by Shias in Iraq. Despite his successes in Islam's traditional heartland, Al-Mansur was unable to reestablish control over Muslims in Spain and Morocco. Instead, a separate state ruled by a member of the Umayyad family was established, forever breaking the political unity of Islam. To mark his victory and the establishment of a new dynasty, Al-Mansur established his capital at the new city of Baghdad in 766.

Frontiers of the Islamic World to 1000 CE

From the earliest decades of Islam, there was a stark but shifting boundary between the Land of Islam (Dar al-Islam) on the one hand and the Land of Unbelief or War (Dar al-Harb) on the other. Between these two worlds no permanent peace was possible; there were only truces for limited periods. Yet this rigorous distinction inevitably blurred once the period of initial enthusiasm was over and the momentum of conquest had slowed down. The letter of the law remained, but practice became relaxed, and the overrunning of all the Lands of Unbelief was postponed from historic to messianic times. Hence, it was possible for a certain amount of stability to emerge along some frontiers or, at least, for a fairly determinate no-man's-land to become recognized. This was the case in Spain between the Muslims of al-Andalus and the Christians of the petty kingdoms of the north of the peninsula and equally so with regard to the Taurus region of Anatolia.

Moreover, Islamic law came to recognize an intermediate status, that of the Land of Treaty Relationship (Dar al-Ahd) applied to non-Muslim states in a contractual relationship with the Muslims, paying tribute to the Muslims but retaining their own autonomy and internal freedom. This was, for instance, the position of the Christian Kingdoms of Nubia (modern Sudan) vis-à-vis the Muslim power in Egypt down to Mamluk times.

Both the Muslims and the non-Muslims left the frontier zones depopulated, with only fortresses and strong points guarded by local irregular troops. The Islamic strong points were called *ribats*, probably meaning "a place for tethering horses" and echoing a verse in the Quran, viii, 62, in which the believers are enjoined to launch against their enemies at the frontier their full strength, including mounted pickets (*ribat al-khayl*).

The ribat is an institution found in the early centuries of Islam wherever there was a frontier,

whether by land or sea, facing powerful enemies in the Land of War. The ribats were frontier forts that also partook of the nature of religious retreats. Fighters for the faith (*ghazis*, *mujahids*) anxious to discharge their obligation of jihad would meet in the ribats for defending the frontiers and for raiding into enemy territory and also for religious and ascetic exercises. Hence, the ribat owes its existence to the unique fusion within Islam of the life of rigorous asceticism and the life of combat against the infidel, and the Islamic jurists were aware of the convergence of the two strands when they analyzed the jihad into a greater jihad (the spiritual fight against the errant ways of the soul) and a lesser jihad (military action against the infidels).

Ribats were to be found in al-Andalus, their legacy includes many places named Rabida or Rapita that still exist in Spain and Portugal. And an origin of the peculiarly Spanish Christian military orders of Calatrava, Santiago, and Alcántara, which had developed in the ninth and tenth centuries from the Islamic *murabits* (people of the ribat) was suggested in 1820 by the Spanish historian of Muslim Spain, José Conde. They were especially thick on the Atlantic and Mediterranean coasts of the Maghreb, from the mouth of the Senegal River to Tripoli. In the Islamic east they were very numerous in Anatolia, central Asia, and Afghanistan, facing the Byzantines, the pagan Turks, and the Rajputs in India.

The ribats on the eastern frontiers of the Islamic world, such as against the Byzantines in Tarsus and against the pagan Turks of the steppes beyond the Oxus and Jaxartes, were manned on a shifting basis by volunteers from the various towns of Syria, Iraq, and Transoxiana, which also provided money and horses for these strong points. The eastern Islamic provinces, because of their proximity to an open and often fluid frontier with the pagan lands of Inner Asia, were the focus of a particularly strong and bellicose Muslim piety. This spirit of jihad there was even stirred by events on the distant Byzantine frontier during the third quarter of the tenth century.

After the Islamic empire was dissolved in the eighth century, the Arab or Muslim control over the faraway parts of the empire such as al-Andalus, Sind, and Inner Asia weakened, and the non-Muslims took advantage of this throughout

the ninth and tenth centuries to try to reconquer portions of these faraway parts.

Muslim Frontier in Spain to 1000 CE

From the Muslim conquest of Spain in 711 until the mid-eleventh century, the frontier between al-Andalus (Muslim Spain) and the Christian kingdoms ran across the northern part of the Iberian Peninsula.

Muslim troops had gained the eastern Pyrenees within the first decade of Islamic rule in the peninsula, when Barcelona, Gerona, and Narbonne had been captured. The Muslims raided into the heart of Gaul (France) until 732 when, in October, Charles Martel defeated an Islamic host under Abd al-Rahman al-Ghafiqli near Poitiers. The Muslims held on in southern France until Pepin the Short recaptured Narbonne in 751.

In 750 a disastrous drought, causing famine, ravaged extensive areas of the peninsula, particularly the central and northwestern regions. This induced many of the Berbers of Galicia to return to their North African homeland. At this point the Christian kingdom of Asturias seized Galicia. The Muslims did not make any further attempts to occupy the lands north of the Duero River but consolidated their power to the south of that river. From then to the tenth century, a century and a half of raids and counterraids laid waste to the no-man's-land that separated al-Andalus and the Christian kingdoms.

The tenth century witnessed the height of Andalusí fame, power, and wealth under three

strong rulers, the first of whom was Abd al-Rahman III ("The Victorious," 912–961). By the 920s he launched an offensive against the Christian kingdoms, sacking Pamplona and inflicting heavy losses on the Basque troops of Sancho Garcés of Navarre in 924.

Abd al-Rahman died at the height of his power and was succeeded by another strong caliph, the scholarly al-Hakim II (961–976). Al-Hakam continued to press the Christian kingdoms with constant raids, keeping his militia strong and dynamic through the continued importation of Berber soldiers. In the early 970s, Al-Hakim received continuous embassies from the king of Navarre, the regent of León, and the counts of Castile, Galicia, and Barcelona, who came to render homage and tribute before the dazzling strength of the greatest power in Europe.

Al-Hakam's death induced a dynastic crisis, leaving the country under the rule of a boy, Hisham II, but in the actual power of the *hajib* (chamberlain), Muhammad ibn Abi Amir, known as al-Mansur. As *hajib* he continued to scourge Christian territory, his raids culminating in the sack of Santiago de Compostela in 997 when he razed the cathedral and carried off its bells to Córdoba. When he died while returning from his last campaign in 1002, he seemingly left the state in a strong position. But his military strength was gained at the expense of disrupting the ethnic balance of power upon which the state's political foundations rested. He professionalized the army by detribalizing it (forcing Arabs into mixed units without regard to tribe or place of origin) and by injecting into it large numbers of newly recruited Berber regulars.

During the same period the pace of change in the Christian zones was much slower, obeying different socioeconomic imperatives. In the eighth century it is possible to distinguish broadly between three zones, differing from one another in social organization and culture. In the west was Galicia, where continuity of settlement had been unbroken from late Roman times and where elements of Roman social organization survived. In the center, a continuous mountain belt, from the Cantabrian system in the west to the Pyrenees, was populated by Cantabrian and Basque mountaineers, who also represented an ancient tradition, one of hostility to the power centers of the peninsula. In the extreme

east was the future Catalonia, an area only lightly garrisoned by the Muslims that in the early ninth century came into the orbit of Carolingian political power and social organization.

Before the famine of 750, with Berbers occupying the mountains of southern Galicia, the Muslims' northern line of defense in the central zone followed a line extending eastward from Saldaña in the present province of Palencia to Amaya, Miranda de Ebro (Burgos Province), and Cenicero.

The medieval legend of the origins of the "Reconquest," interwoven with neo-Gothic strains, places the birth of the movement of resistance at Covadonga, where in 722 a small group of Christians under Pelayo, a Gothic noble, defeated a Muslim column.

Indeed, Pelayo's grandson Alfonso I (739–757) had carved out a small principality in the mountains of Asturias, with its capital in Oviedo, and he began the first tentative steps toward expansion into areas abandoned during the drought of 748–753 by Berbers, or those areas that had not been completely abandoned but were only thinly garrisoned.

In the middle part of the century the Duero Valley became more or less totally depopulated and came to constitute a no-man's-land between the Asturian kingdom and al-Andalus. Around 756, the last year of Alfonso I's reign and the first of that of Abd al-Rahman I, the Christian line (including the buffer zone) followed the course of the Duero from its mouth to Osma and then turned northward, extending into the Basque country. The Islamic frontier, representing the line up to which permanent settlement was encouraged, ran from somewhat north of Coimbra in the west through Coria, Talavera, and Toledo and then swung north to encompass Guadalajara, Tudela, and Pamplona.

A more organized effort at expansion southward was begun in the reign of Alfonso II (791–842), during which time the mountain people began to move down onto the plain to begin small agrarian settlements in what were to become León and Castile, the first stage of which (ca. 800–835) involved the settlement of the headwaters of the Ebro River (Miranda de Ebro, Mena Valley). Under Ordoño I (850–866) the focus shifts westward; the king was said to have directed the settlement of the deserted towns of

Bell tower of la Mezquita in Córdoba, Spain. Muhammad ibn Abi Amir, known as al-Mansur, sacked the Christian city of Santiago de Compostela in 997, razing the cathedral and appropriating its bells for the Córdoba Mosque. (Catherine Jones)

León, Astorga, Tuy, and Amaya with people fleeing al-Andalus. Farther to the east, settlers moved across the Ebro and fortified a line extending from Amaya to Oca.

Farther east, Sancho Garcés I of Navarre (905–925) was able to capture Pamplona and fortify a long line of forts in the foothills of the Pyrenees after the decline of the powerful Banu Qasi clan made such an advance possible. But no further advances were registered during the tenth century, as Abd al-Rahman III was able to turn the Navarrese back in a series of campaigns in the 920s.

In the eastern Pyrenees a number of mountain counties had taken shape under Frankish patronage (Sobrarbe, Ribagorza, Pallars). The Franks had pushed the Muslims out of Barcelona in 801 and stabilized the frontier somewhat to

the south. The future Catalonia remained within the Frankish orbit until the Carolingian collapse of the mid-ninth century made it possible for the southern counts to establish independent hereditary dynasties. In the 870s Guifred the Hairy, a descendant of the Gothic count Borrell of Ausona, had established his family's control over the counties of Barcelona, Gerona, and the mountain territories of Urgell, Cerdàña, and Conflent. In a movement analogous to the settlement of the Duero Valley the plain of Vich was settled, beginning under Guifred's direction in the closing years of the ninth century and continuing into the middle of the tenth century. By 1000 CE the pale of settlement had extended south of Barcelona into the Panadés and west to Segarra.

The eleventh century, the most critical and significant of the Spanish Middle Ages, witnessed a change of sign in the peninsular balance of power. After the death of al-Mansur, the caliphate of Córdoba, still the strongest power in Europe, collapsed in ruins in a matter of years. After a period of struggle and shifting power relations (the *fitna* or anarchy of 1008–1031) the unitary Islamic state was replaced by a shifting constellation of two dozen or so small states, ruled by the so-called Party Kings (*mulúk al-tawâ'if*). The Christian countries were then able to take quick advantage of the fragmentation of Islamic power by first establishing their suzerainty over the Party Kings by exacting tribute and then by renewing the conquest of Islamic territory.

Islamic Frontiers in Anatolia to 1000 CE

After the Battle of Yarmuk in which the Byzantine emperor Heraclius lost many of his best troops, he endeavored to strengthen the Byzantine position in northern Syria, but there were no natural defensive barriers there to hold up

the Arabs. Hence, after 639 Emperor Heraclius adopted a defensive role in order to protect the heartland of Asia Minor and Armenia. Thus, it was the natural barrier of the Taurus Mountains that was to form the normal boundary between Islam and Byzantium for four centuries.

The Muslims dispatched raiding parties or armies (*sawa'if*) into Anatolia from Syria each spring and summer, and their highly mobile cavalrymen often penetrated right across the plateau to Nicea, Armorium, or Samsun. Nevertheless, a rough frontier zone came into existence along the southern edge of the Taurus and its southern outliers like the Amanus Mountains, the Jabal al-Lukkam or "Black Mountain," in northwestern Syria. This latter region was in the first century or so of Islam the stronghold of Christian people whom the Byzantine historians call Maradaites.

Soon after the second Arab occupation of Antioch in Umar I's caliphate (634–644), the Maradaites made an agreement with the Arabs to act as spies and scouts for them and to guard the Amanus Gates against the Byzantines; in return, they were exempted from the poll tax, or *jizya*, normally levied on Christians and were given the right to a share in the Arabs' plunder. Around the year 666, Emperor Constans IV detached them from the Arab side. Justinian II was again able to raise the Maradaites and to get them to raid southward into Lebanon (688 or 689). From the early eighth century, some Maradaites were dispersed through northern Syria and even Iraq as soldiers of fortune in the caliphal armies, while a considerable number of them immigrated to Byzantine territory. In their place, the caliph brought in the Zutt from Iraq (originally Jhats from India).

The main frontier region between the Arabs and the Byzantines comprised the two zones known to the Arabs as, first, the *thughur*, or gaps, a forward zone of strongholds in an area that the Arabs called the *dawabi*, or "outer regions," and second, an inner line of defenses, the *awasim*, or "protective fortresses." In the early period of the Arab conquests, the awasim stretched from Antioch, north of Aleppo to Manbij. Under the Umayyad caliphs, the Arabs concentrated for their annual summer incursions on the plain of Dabiq in the Azaz district of the upper course of the Quwaiq River. A semipermanent

nent forward military base was established there. Administratively, the region of the awasim depended on the military center of Qinnasrin, to the southwest of Aleppo. The whole area was the scene of strenuous fighting during the Byzantine reconquests of the tenth century, and despite the containing actions of the Hamdanid emirs of Mosul and Aleppo and their intermittent successes against the Byzantines, by the third quarter of the tenth century the last Hamdanids lived virtually under a Byzantine protectorate.

Beyond these awasim stretched the marches of the *thughur*, a vaguely delimited region stretching as far west as Tarsus and Massisa and northward and eastward to Marash, Samosata, Nisibin and Malatya. The western parts were known as the Syrian *thughur*, and the eastern ones, those on the upper Euphrates, were known as the Jazira *thughur*. In the Umayyad period, the defense of the Syrian marches was the task of the Syrian government troops based on Damascus, Homs, and Qinnasrin, while the more easterly marches were defended by the northern Arab tribesmen who had settled on the vacant lands of northern Mesopotamia.

When Heraclius retreated northward, he deliberately left the region up to the Taurus depopulated, with only fortresses and strong points guarded by local irregular troops such as the Maradaites. The equivalent Islamic institution to these Greek frontier strongholds was the *ribat*. Along the Syrian and Jaziran *thughur*, the *ribats* existed in fact as centers where fighters for the faith congregated. The region of the *thughur* must have acquired a mixed Christian and Muslim population from Umayyad times onward, with Arab colonists coming in the wake of the Arab armies and settling in the Muslim strong points among the indigenous Christians, Syrians, and Armenians.

Moreover, at times there were quite large-scale movements of whole population groups across the frontiers. In the period immediately after the Arabs overran Palestine and Syria, certain Arab tribal groups, who had been established on the Syrian Desert fringes in pre-Islamic times, preferred to migrate to Byzantine territory rather than become Muslims. In the tenth century a powerful Arab tribe, the Banu Habib, which remained Christian for one or two centuries after

the Islamic conquests, emigrated from the region of Nisibin. After suffering from the exactions and harassments of their kinsmen, the Hamdanids, some 10,000 or 12,000 cavalymen of the Banu Habib, together with their families and clients, migrated northward to Byzantine territory, where they became Christian and were received with open arms by the Byzantines. The Hamdanids were then used as frontier auxiliaries by Byzantium, constituting a useful element of additional military pressure on the Muslims of al-Jazira.

Islamic Frontiers in Northwestern India to 1000 CE

The Arab conquest of the northwestern Indian (now southern Pakistan) kingdom of Sind and southwestern Punjab was completed by 714, and during the following three centuries there was no further extension of Muslim dominion. The second phase of Muslim expansion, beginning with the establishment of a Turkish Muslim dynasty in Ghazni, followed the traditional northwestern routes for the invasion of India.

It was the Arab occupation of Transoxiana (central Asia) in the eighth century that paved the way for the Muslim conquest of India, for it established a link between the Turkish homeland and Islam. From this time the Turks were to play an important role in the Muslim world and were the main force behind the conquest of the subcontinent.

The first inroad into the heart of the area that is now Afghanistan was made by Yaqub ibn Lais, the Saffarid who captured Kabul in 870 and founded Ghazni at about the same time. Kabul was, however, lost by his successor to Hindu rulers known as the Hindu Shahis, whose capital was at Waihind (Ohind), near modern Peshawar,

and whose rule extended to Kabul in the west and the Bias River in the east.

In the meantime the Samanids (874–999) had established themselves at Bukhara and gradually brought the greater part of the territory to the east of Baghdad under their rule. Persian in origin, they favored the Persian language, and thus Persian replaced Arabic as the official language.

Under the Samanids, Turkish slaves gained political and military importance. One of these, Alptigin, rebelled against his Samanid masters and established himself at Ghazni in 962. In 977 Subuktigin, a Turkish slave upon whom Alptigin had bestowed the hand of his daughter, ascended the throne of Ghazni and proceeded to expand his kingdom by annexing adjacent areas in Khurasan, Seistan, and Lamghan. Alarmed at the rising power of the new Turkish principality, Jaipal, Hindu raja of Waihind, took the offensive and advanced toward Subuktigin's capital. The two armies met between Lamghan (modern Jalalabad) and Ghazni in 986. Jaipal was defeated and was forced to agree to pay a large indemnity to the Turkish ruler. Jaipal defaulted and tried to avenge his loss, but he was again decisively defeated, and Subuktigin followed up his success by forcing Jaipal to cede the territory between Lamghan and Peshawar.

Later Muslim historians often represent Subuktigin as a champion of the faith whose chief occupation was the propagation of Islam with fire and sword among the idolators of India. But, in fact, he never crossed the Indus, and the only two expeditions in which he took the initiative were undertaken as measures of reprisal and for the purpose of securing his dominion rather than with any intention of propagating his faith. Subuktigin, however, paved the way for the more

active efforts of his son Mahmud by occupying the key city of Peshawar and building roads leading to the Indian frontiers along which his son marched during his numerous expeditions.

Even more important was the development of Ghazni as a base of operations against India. It reached its zenith in the succeeding reign when it became a center of political power, organized administration, and literary culture, second in importance only to Baghdad in Muslim Asia. Even under Subuktigin it surpassed Bukhara in importance and began to attract a large number of Turks who were to form the spearhead of the attack against the Indian subcontinent.

Subuktigin died in 997, and after a brief struggle his son, known as Mahmud of Ghazni, succeeded him. Mahmud at once turned his attention to India. He had taken part in all of his father's campaigns against Jaipal and knew the weakness of the Indian armies as well as the riches of the kings and temples. The series of invasions he launched against the subcontinent were to carry his armies farther than any previous Muslim ruler had penetrated.

■ Introduction: Conflicts in China and East Asia

In the second decade of the fourth century, Turkish, Xienpei, Tungusic, and Tibetan pastoralists invaded northern China. The ruling Jen dynasty fled to the Yangtze Valley, while the

pastoralist invaders set up 16 ephemeral warring kingdoms on the northern China plain.

The Jen dynasty, now the Eastern Jen, became the first of five successive dynasties to rule

China's Southern empire from 317 until China's reunification in 589 by the Sui.

While southern China during that period was usually united, northern China experienced frequent conflict as the 16 "barbarian" kingdoms contested for supremacy. By 439 the Toba, one of the rival groups, had eliminated all of its rivals and founded the Northern Wei dynasty, which for a century ruled northern China. Northern Wei was very warlike, engaging in several wars in attempts to conquer the Southern empire. Also, the Northern Wei protected China from further invasions by northern "barbarians," engaging in a protracted contest in which Northern Wei destroyed the formidable Juan Juan confederation on the northern steppe.

In 532, a succession crisis caused the Northern Wei to split into two fragments, and these fragments experienced further permutations until the Sui dynasty imposed unity on the north (581). The warlike and aggressive Sui then conquered the Southern empire (589), reestablishing a unified Chinese empire for the first time in almost three centuries.

The Sui sent armed forces to the north, where they defeated some of the eastern Turks; to the west, to establish control over the silk route cities in Gansu; and to the south, reestablishing Chinese rule over Vietnam and engaging in combat with the Cham state on the central Vietnamese coast. The Sui sent probing expeditions to Taiwan and as far south as Srivijaya in Sumatra.

But the Sui badly miscalculated when they attacked the Kingdom of Koguryo, which straddled the Yalu River in Manchuria and northern Korea. The second Sui emperor, Yangdi, sent three successive massive armies (claimed to have included up to half a million men each) against Koguryo in 612, 613, and 614. The Koguryo inflicted crushing defeats on the Chinese armies. Then, in 615, the eastern Turks delivered a stunning defeat to Yangdi's forces. This defeat led to Yangdi's assassination and the fall of the Sui dynasty.

After a civil war the Tang dynasty succeeded the Sui. Like the Sui, the Tang was expansive and aggressive but had learned from the Sui's experiences and were luckier. After three more failed invasion attempts, the Tang allied itself with Silla, then the smallest of the three Korean kingdoms. In a series of protracted campaigns (630–668),

CHRONOLOGY FOR CHINA CENTERED CONFLICTS, 300–1000 CE

Chronology: All dates are CE (Common Era).

- 304–317—"Barbarian" invasion of northern China
- 304–439—Warfare among 16 "barbarian" kingdoms in northern China
- 317–589—Five successive dynasties rule the Southern Chinese empire
- 439–535—Toba Northern Wei dynasty in northern China
- 581—Sui unite northern China
- 589—Sui conquer the Southern empire and create the reunified Chinese empire
- 589–618—Sui dynasties
- 612, 613, 614—Koguryo defeats Sui invasions
- 615—Eastern Turks defeat Sui
- 618–907—Tang dynasty
- 630–668—Tang-Silla alliances unify Korea
- 630–690—Tang destroys eastern Turk and western Turk empires, forces Tibet to become tributary, annexes the Tarim Basin, and extends Chinese power into central Asia
- 669–674—Silla frees Korea from Tang rule
- 683–705—Rule of Empress Wu
- 751—Nanjao Kingdom defeats Chinese army at Battle of Dali Lake; Arabs defeat Chinese army at the Battle of Talas
- 755–763—An Lushan's Rebellion
- 883–906—Huang Chao's rebellion begins a period of turmoil and civil war that leads to the collapse of the Tang dynasty
- 907–960—Period of division, Ten Kingdoms and Five Dynasties
- 960–1126—Northern Song dynasty; Khitan Liao dynasty in far north

—Wilfred J. Bisson

the alliance of Tang and Silla defeated a counter-alliance of Koguryo, Paekche, and Yamato (Japan) that created the first unified Korean kingdom under Silla's rule in 668. Silla then turned against the Tang, fighting a successful five-year war to throw off Chinese suzerainty.

The early Tang dynasty, like the Sui dynasty, extended its power in every direction. In the 630s, the Tang destroyed the eastern Turk empire, and in 657 they also destroyed, with the alliance of the Uighurs, the western Turk empire.

The Tang annexed the Tarim Basin and extended Chinese power beyond the Pamir Mountains, almost to the Ferghana Valley. Tang power forced the Kingdom of Tibet, which had been unified in 600, to accept a tributary status. In one amazing exploit, a Tang force crossed the Himalayas into India, captured an Indian king who had offended a Chinese envoy, and brought the king back to China for punishment.

Empress Wu (r. 683–705) was one of the more successful of the warlike early Tang rulers. Under her rule, Chinese power was felt from the southeastern peninsula deep into central Asia.

The power of the Tang dynasty began to slip after 700. Tibet became more restive, and a strong kingdom, Nanjao, challenged China in the southwest. Most ominously, the Arabs who in the previous century had conquered an empire as great as that of the Chinese were consolidating their power in central Asia. A power struggle developed among the Tibetans, the Turks, the Arabs, and the Chinese for dominance in central Asia. Tang power was humbled by the nearly simultaneous defeats of Chinese armies at the Battle of Lake Dali by the Kingdom of Nanjao in Yunnan and at the Battle of Talas by the Arabs in the Ferghana Valley.

From 755 to 763, China was convulsed by the An Lushan Rebellion in which both Chinese and “barbarian” armies fought devastating battles throughout northern China. With the aid of its one loyal Turkish ally, the Uighurs, the Tang dynasty survived, but it never regained the power of the early Tang. Chinese power contracted to the Han provinces, and the dynasty was required to pay tribute to its Uighur allies, who took over the Chinese outposts in the Tarim Basin.

The weakened Tang dynasty survived nearly another century and a half. In 883, another protracted series of rebellions began. These rebellions led to civil wars that ravaged the empire until it was finally overthrown in 906.

The Tang dynasty was followed by more than half a century of division, the Period of Ten Kingdoms and Five Dynasties. During this period, rival warlords contended for dominance, and another northern “barbarian” people, the Khitan, seized some of the northern territory. This period of turmoil ended when another strong dynasty, the Song, reunified China in 960.

But the China of the Song was much smaller than that of the Tang at its most expansive.

Conflict between States and Dynasties, Northern and Southern China, 220–589 CE

The long period from 220 to 589 CE in China was a time of disunity. In the north, there existed at least 16 separate kingdoms, and in the south, four independent dynasties rose and fell. This north-south division continued until 589, when the south was conquered by the north.

The disunity had begun to manifest itself at the end of the Han dynasty, during the Three Kingdoms period. During this period, the kingdoms of Wei (220–265), Shu (221–263), and Wu (222–280) vied against one another for the upper hand. Wei annexed Shu in 263; however, its ruler was in turn forced to abdicate by the Sima family, who founded instead the Western Jin dynasty (265–317). Fifteen years later, in circa 280, the Jin forcibly annexed Wu, thereby unifying China. Thereafter, for approximately half a century, peace and stability prevailed until the reign of Jin Huidi.

First, Empress Jiahou and her clan monopolized the political scene; then, the eight princes, themselves powerful warlords stationed outside the capital, rebelled. In their struggle for the throne, they either formed alliances among themselves or fought against one another. To strengthen their hold, they invited the troops of the Xiongnu and Xianbei (nomadic non-Chinese tribes living on the northern periphery of the Jin territory) to join forces with them. During the 16 years of this so-called Rebellion of the Eight Princes (291–306), war raged around Luoyang and Chang'an, destroying the large area north of the Yangtze River. Eventually, the Xiongnu and Xianbei, along with other nomadic non-Chinese tribes (the Qiang, Di, and Jie), migrated southward and settled among the Chinese within the Jin boundary. Some of these “barbarians” were

assimilated by the Han culture, even going so far as to serve or fight for the Jin government. Others, however, were often suppressed, exploited economically, or forced into servitude by the Chinese, and this was a constant source of resentment. In 311, the Xiongnu attacked Luoyang and captured the emperor Jin Huaidi, while the escaping royal entourage and Jin bureaucrats were killed by another rebelling tribe, the Jie. The surviving Jin government moved to Chang'an, but in 316 the Xiongnu attacked again and captured the last emperor, Jin Mindi, thus bringing to an end the rule of the Western Jin. Henceforth, the north was ruled by a succession of kingdoms, many of whose rulers were non-Chinese. Meanwhile, in the south, the dispossessed Jin nobility and great clans sought refuge across the Yangtze River. Here, rallying around the prince of Langya Sima Rui at Jiankang, they established the Eastern Jin (317–420).

In the absence of the Jin government in the north, chieftains of the Xiongnu, Xianbei, Qiang, Di, and Jie, together with Chinese clan leaders and settlers and refugees, seized territory. Proclaiming themselves true successors to the throne, they established their own kingdoms that survived for varying lengths of times. These northern states (established between 304 and 439) were collectively known by Chinese historians as the Sixteen Kingdoms of the Five Barbarians. They were the kingdoms of the Former Zhao, also called the Han (304–318), Later Zhao (319–352), Former Yan (337–370), Later Yan (384–409), Southern Yan (398–410), Northern Yan (409–436), Former Qin (351–394), Later Qin (384–417), Western Qin (385–431), Xia (407–431), Former Liang (354–376), Later Liang (386–403), Southern Liang (397–414), Northern Liang (397–439), and Western Liang (400–421). Not included in the group were another three states: Chenghan (303–347), Western Yan (384–394), and Ran Wei (350–352). In the midst of the continuing wars and turmoil, the Former Qin rose to power and came close to unifying the north. However, in 383, at the Battle of Feishui, the Eastern Jin countered their attack so powerfully that the Former Qin suffered enormous losses and soon after retreated and began to collapse. Their formerly subjugated peoples now broke away, and the north again disintegrated into

many states. In the midst of this chaos, the Xianbei tribe led by Tuoba Gui, Tuoba Si, and Tuoba Tao expanded its territories and founded the Northern Wei (386–534). Tuoba Tao proceeded to unify northern China between 425 and 439.

In the south, the Eastern Jin attempted to recover the areas north of the Yangtze River that had been occupied by northern invaders in 354, 356, and 359 but without much success, reclaiming some territory only after the defeat of Former Qin in the Battle of Feishui. In 409, Jin general Liu Yu launched a campaign in the north and conquered the Southern Yan. He seized the throne of the last Jin ruler and founded the first of the Southern dynasties, the Song dynasty (420–479). In 450, the Northern Wei waged the Battle of Guabu against the south. The Song dynasty was seriously at risk but was able to withstand the attack. However, both sides suffered heavy losses. As a result, for about 20 years the north and the south were in a stage of equilibrium, as neither was able to defeat the other. The Song dynasty was further weakened by internal political struggles. After a series of ruthless killings among the rival Song princes, Song general Xiao Daocheng took control and established the Qi dynasty (479–502), the second of the Southern dynasties. In time, however, this dynasty suffered a similar fate. A clansman of the Qi royal family, General Xiao Yan, seized power and founded the third and longest dynasty, the Liang dynasty (502–557).

While dynastic changes were taking place in the south, the north was also fragmenting. In the capital, the Xianbei ruling class wanted to embrace the Han culture, while the Xianbei warriors stationed on the northern border of the Northern Wei objected to this, and seeing themselves as becoming increasingly marginalized, they rebelled. Subsequently, the Northern Wei broke up into the Eastern and Western Wei between 534 and 535. Wars between the two states lasted for about ten years. Both states were torn apart by internal power struggles and were succeeded, respectively, by the Northern Qi in 550 and the Northern Zhou in 557.

In the south, the Liang dynasty was also badly shaken by a rebellion. A defecting Eastern Wei warlord, Houjing, who had sought the protection of the Liang dynasty, killed the Liang emperor and controlled the Liang for four years (549–552). Xiao

Yi, a brother of the killed emperor, secured military aid from the Western Wei by ceding territory and successfully suppressed the rebellion, but his rule was ended by his nephew, who joined forces with the Western Wei to establish the Later Liang dynasty. However, Xiao Yi's son was supported by a Liang general, Chen Baxian, who eventually removed the heir and founded the Chen dynasty (557–589), which was also the last of the four Southern dynasties. Meanwhile, Emperor Wudi of the Northern Zhou set about annexing other states. He defeated the Northern Qi in 577, dying shortly afterward. The father of his daughter-in-law, Yang Jian, ousted his grandson and heir to found the Sui dynasty (581–618). Yang Jian continued the momentum of unification set in motion by Wudi. Yang Jian conquered the Chen dynasty and, in doing so, in 589 succeeded in bringing to an end the north/south division.

Silla and the Wars for Korean Unification

By the fifth century a long process of political consolidation on the Korean peninsula had resulted in the emergence of the three kingdoms of Koguryo, Paekche, and Silla (as well as a grouping of minor city-states in the southwest called the Kaya, or Karak, Confederacy). These three kingdoms, all ruled over by central monarchies, emerged as rivals for control of the peninsula's limited resources, a process that culminated in the wars of unification of the seventh century and finally the unification of most of the Korean peoples under Silla rule.

In rough geographic terms, Koguryo occupied the northern half of the peninsula, extending into what is today Northeast China. Paekche controlled the peninsula's southwest, and Silla controlled its southeast. The early period of this rivalry seemed to portend a Koguryo victory. During the late fourth and fifth centuries a succession of powerful and effective Koguryo monarchs, most prominently King Kwanggaeto (r. 391–413), strengthened central authority and greatly extended the kingdom's territory. In 427 Koguryo transferred its capital from its ancestral homeland along the Yalu River in Northeast China south to what is today Pyongyang along the P'ae (or Taedong) River, and in 475 Koguryo even captured the Paekche capital of

► ELITE WARRIORS OF SILLA—THE HWARANG

The Hwarang (often translated as “Flower Youth”) were bands of young Silla noblemen, some of whom played central roles in the military campaigns against Kaya, Paekche, Koguryo, and Tang China that culminated in Silla's unification of the Korean peninsula in 676. The heroic exploits of the Hwarang, recounted in such works as the thirteenth-century *Samguk Yusa* (*Memorabilia of the Three Kingdoms*), have ensured them a prominent place in Korean history and imagination. The exact meaning of the term is unknown but likely refers to the legendary beauty of the Hwarang initiates (*hwa*, meaning “flower” in Sino-Korean). Originally the primary activity of these noble bands seems to have been song, dance, poetry, and a commitment to ethical living.

Although the earliest Hwarang bands were composed of young women, they became exclusively male in the sixth century. The Hwarang also became associated with worship of the Maitreya Buddha, the Buddha of the future. As rivalries among the three kingdoms of Korea intensified in the late seventh and early eighth centuries, the Silla monarchy took tighter control over the Hwarang, training them in the military arts and inculcating them with a patriotic fervor, making the elite Hwarang a sort of training ground of Silla leadership. Undoubtedly the most prominent Hwarang was Kim Yusin (595–673), whose brilliant generalship made him a central architect of Silla unification.

—Daniel C. Kane

Hansong (near present-day Seoul), killing its king Kaero.

Both Silla and Paekche felt the pressure of Koguryo expansion. In 475 Paekche was forced to shift its capital farther south to the fortress town of Ungjin (present-day Kongju). More importantly, around 490 Silla and Paekche forged a political and military alliance, one that successfully fended off Koguryo's southerly ambitions for more than half a century. In 551 this alliance fell apart in acrimony when Silla seized territory won from a united Silla-Paekche campaign against Koguryo in the Han River basin. This sudden act of boldness by Silla can only be seen in the context of the growing strength of the Silla state.

In 500 Silla seemed the unlikely vehicle of Korean unification. Unlike his counterparts in Koguryo or even Paekche, the Silla monarch was still largely beholden to powerful aristocratic clans. Furthermore, Silla's location in the southeast meant that it often fell victim to attacks by the Wa, a marauding peoples who emerged from their bases in Tsushima or nearby Japan to raid the Silla coast. Its geographical setting also meant that it was historically more isolated from regular contact with Chinese dynasties, potential sources of material and cultural support.

But in the sixth century came the two reform-minded and effective Silla monarchs Pophung and Chinhung. In 527 King Pophung formally adopted Buddhism (although Silla had been exposed to Buddhism more than a century earlier via Koguryo). In Silla the new faith was soon utilized to bolster royal authority. The Silla kings began to portray themselves as living Buddhas and Korea as a Buddha land, and they also promoted the state protection aspects of the faith. In an attempt to strengthen the state Pophung also instituted Chinese-style bureaucratic reforms and strengthened cooperation between the king and aristocracy by formalizing aristocratic privileges. Drawing on this new strength, his successor King Chinhung expanded Silla territory. Betraying its alliance with Paekche, Silla seized the Han River basin in 551, and in 562 he defeated the last of the Kaya states.

It is also King Chinhung who is credited with instituting the Hwarang corps that proved an important component of Silla's growing

KOREA'S THREE KINGDOMS, CIRCA 650

strength. Beginning as bands of young initiates dedicated to song and poetry, by the late sixth century the Hwarang had evolved into a training ground for elite warriors and political leaders drawn from the aristocratic classes.

The seventh century opened as a period of violent stalemate, with none of the three kingdoms able to dominate its rivals. For its part, Koguryo from 598 to 612 was preoccupied by massive offensives by the Chinese Sui dynasty. Koguryo ultimately prevailed, and Sui's tremendous losses helped topple that young dynasty and usher in the Tang in 618. But the first Tang emperor, Taizong, soon revealed himself equally

determined to defeat a recalcitrant Koguryo. A moral justification for invasion was provided in 642 when the Koguryo military strongman Yon Kaesomun (by all accounts a brutal and ruthless figure but one of surpassing military skill) murdered the Koguryo king, installed a puppet on the throne, and seized control of the state. But as with his Sui precursor, Tang Taizong failed in his costly attempt to subdue Koguryo in 645. Ultimately such Koguryo successes played into the hands of Silla.

Following the bitter end to its alliance with Silla in 551, Paekche turned its diplomatic attentions to Japan, forging an alliance with that kingdom that continued until the fall of the Paekche state. In the early seventh century Paekche also allied with Koguryo and began to harass Silla strongholds in the Han River basin. Silla's attempts to ally itself with Japan and then Koguryo fell on deaf ears. Diplomatically isolated, Silla then turned to the Tang dynasty, which was still smarting from its 645 defeat by Koguryo. In 660 Silla brokered an alliance with Tang to launch joint invasions, first of Paekche and then Koguryo. A combined land and sea invasion of Paekche in 660 quickly resulted in that state's fall despite the last-minute aid of Japanese troops. The fall of Koguryo was hastened by its material exhaustion following its protracted engagements with Sui and Tang and then by the death of Yŏn Kaesomun around 666. Upon Yŏn's death civil war erupted among his several sons, with one appealing for aid from Tang and guiding in Chinese forces. A Tang-Silla invasion of Koguryo ended with Koguryo's final defeat in 668.

Silla's relations with Tang soured soon after the fall of Paekche and Koguryo when Tang attempted to create a colony out of the Korean peninsula reminiscent of the Chinese commanderies in the region during the earlier Han dynasty. Unwilling to accept this state of affairs, Silla launched a campaign to expel the Tang forces. A series of Silla victories resulted in the withdrawal of Tang forces from Korea in 676 and the unification of the peninsula for the first time. Meanwhile in what is today far northeastern Korea and the Russian Maritime Provinces, remnants of the defunct Koguryo state combined with elements of Malgal peoples to formally

establish the state of Parhae in 713. Until its fall in 926 this state would enjoy an independent and nearly contemporaneous existence alongside Unified Silla, and thus some Korean historians refer to the period of Parhae and Unified Silla as the Era of Northern and Southern Dynasties.

An Lushan Rebellion

The An Lushan Rebellion took place between 755 and 763 during the Tang dynasty (618–907). In Chinese history this event is known as the An-Shi Rebellion to include another major rebel leader, Shi Siming. Although the revolt did not topple the dynasty, it inflicted the Tang a heavy blow by shaking its imperial foundations, a factor that led to its decline.

By the mid-eighth century, Tang China was unrivaled in the world for its wealth, power, and stability. However, serious problems slowly emerged. The concentration of land in the hands of large landowners resulted in small landholders becoming tenants, indentured laborers, or migrating beggars. Scholars estimate that more than 5 million such migrants roamed the empire

THE AN LUSHAN REBELLION, DECEMBER 16, 755–FEBRUARY 17, 763

by the mid-eighth century. This phenomenon alone impacted the Tang military system, which required peasants to serve in the army. With no land, few peasants were willing to perform this obligation, which compelled the Tang to adopt a new system of hiring professional soldiers. This special tie enabled commanders, such as An Lushan, to enjoy loyalty from those soldiers who expected booty and benefits from commanders.

Political corruption was also prevalent during the Tang dynasty. Xuanzong's long rule eroded his enthusiasm for handling tedious political issues. He became infatuated with Lady Yang and left state routines to corrupt officials and eunuchs. The ruffian Yang Guozhong, Lady Yang's cousin, even became the prime minister.

At the provincial level, it was not unusual for a rich man to purchase an official title. On the one hand, these weakened Tang's administrative effectiveness; on the other hand, they were used as a pretext for An Lushan to stage a rebellion.

The immediate cause for the rebellion was frontier military arrangements. In the 740s the Tang court appointed non-Chinese generals to command frontier garrisons on the grounds that they were brave and maintained no political affiliation. This allowed a number of non-Chinese, including An Lushan, to gain military commands. Within a decade, An was conferred commanderships in the northern Chinese frontier. It was from this base that he eventually launched his rebellion.

This Song period reproduction of an eighth-century landscape depicts Tang dynasty emperor Xuanzong (the mounted figure in foreground, crossing bridge) fleeing with his party to Sichuan. An Lushan's attack on Chang'an in 756 forced Xuanzong to evacuate the capital. (Werner Forman/Art Resource, NY)

An Lushan rose in revolt against the Tang in 755 by commanding 150,000 troops to march southward with the excuse of removing corrupt officials from the royal court. Seized with panic, the Tang rushed to a fight with newly recruited soldiers who were mercilessly routed. In a few months An occupied most of the Yellow River basin, including the strategic city of Luoyang, where he proclaimed himself emperor of a new dynasty, Dayan.

However, An Lushan was blocked by the Tang troops at the impregnable defensive mountainous pass called Tongguan. At this crucial moment, the Tang court made a disastrous decision by ordering those troops to attack An on flat land. The troops were mercilessly beaten. As a result, the road to the capital of Chang'an lay open. An pressed forward and occupied the capital in 756. Emperor Xuanzong fled to Sichuan, but on his way his mutinous troops killed both Yang Guozhong and his cousin Lady Yang. This incident led to a transfer of power to the crown prince, who escaped to Lingwu (in present-day Ningxia). In 756 he assumed the emperorship as Emperor Suzong, and during the next six years he organized an army to fight An and his rebels.

From 756 to 762 much of northern China was plunged in bloody wars, and millions died. As it turned out, An Lushan was murdered by his subordinates who supported his son An Qingxu.

➤ AN LUSHAN, 703–757 CE

An Lushan epitomizes the Tang empire's multiculturalism. His non-Chinese background has long been known. However, recent studies further trace his paternal origin to Sogdian and his maternal side to Turkish ancestry. After his father died, his mother brought him to Manchuria where he adopted his stepfather's surname of An. His contact with various cultures enabled him to acquire fluency in six different languages.

An Lushan joined the Tang army and rose from the ranks until becoming the commander of Pinglu (present-day Liaoning), Fanyang (present-day Hebei), and Hedong (present-day Shanxi). He became a favorite of both Emperor Xuanzong and his concubine Lady Yang. One story is often cited to show An's shrewdness for imperial favor. When the emperor asked about his fat body (more than

300 pounds according to one source), An replied that "inside is nothing but a big loyal heart to my emperor." As a result, Xuanzong trusted him. The emperor never imagined that An would someday betray him.

An's rebellion did not gain him popular support. On the contrary, he became notorious when he ordered the sack of cities and slaughter of civilians. Ironically, he became paranoiac after he entered Luoyang and frequently ordered the flogging and execution of his subordinates. His volatile temper is diagnosed by modern doctors as a symptom of diabetes due to obesity. He had ulcerous warts all over, a factor that eventually left him blind. His explosive rage that terrorized his entourage finally killed him.

—Patrick Fuliang Shan

The division of the rebellious camp gave the Tang an opportunity to mobilize soldiers to recover both Chang'an and Luoyang in 757. Meanwhile, loyalist officials coordinated in their defense and resistance. For example, Zhang Xun guarded Suiyang (present-day Shangqiu) for almost a year with a small contingency, smashing the enemy's plan to invade southern China. Zhang Xun fought to the last man, for which he was canonized by the Tang as a national hero. In 759 An Qingxu was killed by Shi Siming, who crowned himself the next rebel emperor. Shi recaptured Luoyang and planned to retake Chang'an. Nevertheless, Shi Siming was murdered in 761 by his own son Shi Chaoyi, who became the last rebel emperor. In the next two years Shi Chaoyi was pursued by Tang troops and suffered defections by his own soldiers. In despair, Shi Chaoyi committed suicide in 763, formally ending the rebellion.

The An Lushan Rebellion was a turning point in Tang history. Many regions were depopulated as many millions of civilians lost their lives, and those who survived suffered severe economic and social dislocation. Consequently, the Tang financial machinery malfunctioned. The war forced many northerners to take flight to the south, shifting Tang's economic center to the Yangtze River basin.

The most devastating impact of the rebellion was the formation of the warlord system. When the rebellion was suppressed in 763, about 75 percent of the governors in the provinces were military men. Soon after, the Tang created 43 military commanderships throughout the empire (only 10 on the frontiers before the rebellion). Many of those commanderships became hereditary, and the holders of these offices enjoyed semi-independence. This chronic militarism deeply divided the Tang empire into autonomous domains free from the control of the central government. The Tang had to depend on foreign or barbarian troops for its own defense, echoing the similar situation of late imperial Rome.

The revolt forced the overstretched Tang empire into contraction and made it a defensive rather than an expanding empire. The rebellion encouraged a number of ethnic states to invade Tang China, and the Tibetans briefly occupied

Chang'an in 763. Along the southern frontier, while Tang soldiers were moved to the north to fight the rebels, Nanzhao started to take over the vacated territories. As central Asia fell into Turkish or Tibetan hands, commerce on the formerly thriving Silk Roads suddenly slackened. Consequently, the Tang empire decayed. Although it existed in name for another century, its influence and prestige no longer existed. It was able to survive the next 100 years because southern China was not impacted by the rebellion.

Japan's Military and the *Emishi* Pacification Wars

Until well into the ninth century the northeastern third of Honshu remained outside the Japanese imperium as a hazy frontier zone inhabited by a people known to the court as the *emishi*. While cultural, political, and economic interaction between this region and the rest of Japan was ongoing from prehistoric times, efforts to absorb the *emishi* and their homelands began in earnest during the second half of the seventh century, after the establishment of the imperial state.

The first such efforts centered on the creation of outposts (usually called forts or stockades in English) and the transplanting of households from eastern and northeastern provinces into the territory. These outposts were fortified, defended by government troops, and served as places into which settlers could

► WHO WERE THE *EMISHI*?

The *emishi* inhabitants of the northeastern frontier region were politically, culturally, and linguistically distinct from the peoples of central and western Japan, but their ethnic identity remains a matter of debate. The issue is, in fact, largely moot, for the term *emishi* was primarily a political appellation, not an anthropological one. It referred to peoples as yet outside the Yamato polity without regard for race.

Although there appears to have been considerable continuity of material and linguistic culture across northern Honshu and Hokkaido, the indigenous societies of the region were organized into tribal villages, which functioned independently of the others. When necessary, related tribes could combine into short-lived federations, but the tribal structure remained intact within the larger organization. At other times even related tribes were regularly at odds—even at war—with one another.

Emishi ethnic identity emerged as a product of interaction and conflict with the expanding Japanese imperial polity. Similar processes also defined two later ethnocultural groups in the same region: the *ezo* of the medieval era and the *Ainu* of early modern and modern times. While there is clearly significant cultural and genealogical overlap between these three groups, there was also substantial diversity between them, within each, and between each and the rest of the Japanese. It is therefore anachronistic and meaningless to attempt to project modern ethnic labels such as “Japanese” or “Ainu” back onto the *emishi* peoples of the pacification era.

—Karl Friday

retreat in times of danger, but initially they supported a mostly nonbelligerent diffusion of imperial subjects and authority into the frontier.

This more or less passive approach ended in 709, when the court began sending armies into the region to build roads and intimidate uncooperative residents. From this time forward, violent confrontations with the *emishi* became more frequent, as the court’s objective shifted from simple absorption to military conquest and subjugation. In 774 the court committed itself—albeit with some internal opposition—to a policy of pacification that would take more than three decades to complete. On at least ten occasions

between 774 and 811, expeditionary forces marched northward to pacify the *emishi*, meeting a mixed record of victories and defeats. The last campaigns, under Sakanoue Tamuramaro in 801 and Funya Watamaro in 811, were, however, pronounced successful. The court thereafter officially declared the *emishi* to have been pacified, and the frontier to have ended.

In fact, the notion of a pacification era was largely a creation of court oratory and propaganda, bounded on both ends not by meaningful changes in circumstances in the northeast but by government declarations. Rhetoric notwithstanding, court expansion into the region continued along much the same lines as before and after the campaigns, as did *emishi* resistance.

Ironically, the subjugation efforts proved to be between both the first and the last activities of the imperial polity in its original form. By the time they ended, the state was undergoing profound changes to its military institutions, its tax collection mechanisms, and its apparatus for central and local government decision making. In fact, the court’s ninth-century efforts to complete the assimilation of the northeast ultimately gave virtually the whole of its machinery for local rule over to *emishi* leadership, a process that foreshadowed what happened elsewhere in the country during the tenth to thirteenth centuries. During the eleventh and twelfth centuries, successive houses of *emishi* descent—the Abe, the Kiyowara, and the Fujiwara—were able to establish nearly autonomous satrapies in Mutsu province, which endured until Minamoto Yoritomo’s northern campaign in 1189. Thus *emishi* autonomy ended only as the court’s exclusive grip on authority in the provinces ended, which occurred in the medieval era.

► THE *RITSURYO* MILITARY SYSTEM

The imperial state legal codes (*ritsuryo*), promulgated in 702, defined an elaborate military apparatus centered on a militia composed principally of peasants conscripted as part of their normal tax and corvée obligations and registered in provincial regiments, or *gundan*. The majority of the troops attached to these militias spent most of their year tilling their fields and were called up in rotation for training and service for 35 days each year.

In time of war, an expeditionary force was knit together from temporarily mobilized provincial regiments under staff officers holding temporary commissions. At the close of a campaign the officers' commissions expired, the army was dissolved, and the troops were returned to their homes. This militia-based system enabled the imperial court both to maintain a near-monopoly on military manpower and the use of force and to

muster very large-scale fighting forces when needed without straining its agricultural base the way a standing army would have.

Tactically, the imperial armies were predominantly light infantry that fought with bow and arrow from behind portable standing wooden shields. These bowmen were augmented by other foot soldiers bearing spears, by bow-wielding cavalry, and by a somewhat mysterious artillery piece called an *ōyumi* or *do*, which appears to have been some sort of platform-mounted crossbow on the order of the Roman ballista. An army of this sort is formidable in pitched battles, particularly on the defensive. But it is logistically ill suited to long offensive campaigns because of its size and because it draws as its manpower the same farmers who produce its food and other supplies.

Chinese Foreign Relations

Chinese foreign relations between 300 BCE and 1000 CE demonstrated multiple characteristics: they went through many transitions, and policies varied toward differing foreign peoples. However, there was also consistency to foreign relations. The cornerstone of Chinese foreign relations was the so-called tributary system, and in the long run the tributary system led to military conquest, new trade, and the spread of ideas, which in turn brought together more closely the different communities in and around the Chinese world.

The tributary system originated long before 300 BCE, at least in the period of Western Zhou (eleventh through eighth centuries BCE), where the lesser lords presented local products from their native places to the Zhou ruling house as

tributes. It was a way to honor the Zhou's superior power and its suzerain claim to legitimacy. The Han (206 BCE–220 CE) inherited the idea and on it based their foreign policy. When the policy developed into a system, it became the tributary system. Under the system, the Han offered military protection and political recognition to lesser polities surrounding its empire in exchange for their pledge of loyalty and acceptance of the status as vassals. Loyalty was manifested in many ways, including the vassal's frequent trips to the Han capital for imperial hearings, offers of local products as tributes, the sending of a vassal prince to Han as hostage, and the adoption of the Han calendar. The vassal was usually left alone subsequently, allowed to administer his own domain and pass it along the family line. During the Han period, the tributary system bonded together many regimes around the empire. After taking shape, the tributary system remained the basic framework of Chinese foreign relations for the many dynasties that followed, albeit with some minor modifications.

In the tributary system, the bond between the suzerain ruler and the vassal varied from individual to individual and from time to time. Geographical distance, political importance,

➤ HAN CHINESE MARRIAGE ALLIANCES

Marriages for political purposes played a very important role in foreign relations in almost all ancient societies, but in ancient China the practice of marrying imperial princesses to rulers beyond the border was especially common. The practice, known as *Heqin*, not only became a cornerstone in Chinese foreign relations but also became the stuff of legends. Dramatic stories of princesses who made the ultimate sacrifice for the wellness of the country captured the Chinese imagination. One such princess was Wang Zhaojun of the early Han dynasty. Wang was among the emperor's large harem and was chosen, according to the legend, because the emperor did not realize how beautiful she was. Her marriage with the Xiongnu Khan secured a peace for several decades. The other well-known princess in the *Heqin* diplomacy was Princess Wencheng of the Tang dynasty, who was married to the ruler of the then-powerful Tibetan kingdom, Songtsan Ganbu. Wencheng not only sealed a vital alliance between the Tang and Tibet but also was instrumental in the cultural exchanges between the two countries. The stories of Wang Zhaojun and Princess Wencheng became favorite subjects in the Chinese literature and arts and continue to be popular today.

—Yi Li

balance of power, and economic vitality often had a bearing on such bonds. The weaker and smaller regimes in Korea, located right next door to the Central Plain, were usually placed under the more direct watchful eye of the Chinese rulers. The southern Xiongnu, who started paying tributes to the Han in the first century BCE, eventually became absorbed in the Han agricultural society. The tribal peoples in the Red River basin in today's Vietnam, on the other hand, had long been under the direct rule of China but became a tributary vassal after winning independence in 939. Meanwhile, many regimes across the vast regions west of China once had pledged loyalty to the Tang emperor (618–907) but switched their loyalty to the Arabic caliph after the 751 Battle of the Talas River.

In addition, the emperor in China did not always play the master in the working of the tributary system. The identities of lord and vassal

depended on the balance of power between the interacting parties. After political unity fell completely apart in 317, rampant disorder left the regimes in China vulnerable to attacks by the nomads. After 415 the Tuoba tribe of the nomadic Xianbei restored order as the Northern Wei dynasty and extracted tributes from lesser powers around its empire, both Chinese and non-Chinese. The Tang dynasty (618–907), which not only continued but also expanded and perfected the tributary system, was partly non-Chinese in its origin. While both the Tuoba and the Tang might have adopted the Chinese ways, the Chinese emperor did not always have the upper hand in the tributary system. After the destructive An Lushan Rebellion in the mid-eighth century, the Tang court survived only at the mercy of the regional powers and non-Chinese forces, noticeably the Tibetans and the Uighurs. The large payments that the Tang had to make in exchange for peace often raised questions on whether the “barbarians” were paying tributes to the Chinese emperor or the other way around.

While the tributary system was the overtone in China's foreign relations, the Chinese were also related to their neighbors in many other ways. First of all, the power of the Chinese imperial state waxed and waned at a different pace from its neighbors; as a result, a tipping of the balance of power often led to military conquests. Under the Qin and Han (221 BCE–220 CE) and then under the Sui and Tang (587–917), China was on the offensive but was on the defensive in the period in between. The continuous seesaw battles resulted in frequent cross-cultural interactions between them. Movements of peoples from one place to another became accelerated, and trade prospered. The differences between the agricultural Chinese on the one hand and the pastoral nomads in the north and tribal peoples in the south on the other hand generated great incentives for trade. Small-scale spontaneous trade must have long existed, but it was the participation of the government that propelled the foreign trade to a much higher level. The trade developed best along two roads: the land road that cut through Inner Asia and connected China to the lands of India, Persia, and as far as to Rome and the sea route that

reached out to Southeast Asia and from there to the India Ocean. Because the main product that traveled along these trade roads was Chinese silk, these became known as the Silk Roads. Many communities along the Silk Roads thrived, and foreign imports shaped Chinese society in many ways. Dunhuang, an oasis town in the Gobi desert along the land Silk Roads, was once the second-largest city in the Tang, with a population of 700,000. Toward the tenth century, however, the sea route gradually prospered, and the Song dynasty had a special office in the southern port city of Guangzhou overseeing the maritime trade.

Moving along the Silk Roads were not only people and commodities but also ideas. Many other peoples were attracted to the better-developed Chinese culture, adopting the Chinese political and economic systems, writing, and philosophy. The Tuoba people probably went through the most thorough process of sinicization, as they, having settled down in China proper since the fifth century, took up the Chinese language, institutions, and customs. Another example was the spread of Chinese culture to Vietnam, Korea, and Japan, a process beginning in the first century BCE. The Japanese adoption of Chinese culture climaxed in the seventh century, when the Taika Reform introduced into Japan the centralized government system, a public landowning system, Chinese writing, and Confucianism. Even the capitals of Japan, first Nara and subsequently Heian-kyo (Kyoto), were miniatures of the Tang capital of Chang'an in China. But the spread of cultures was not at all one-way traffic; many foreign ideas were introduced into China, the most significant of all was Buddhism. First introduced to China by the merchants traveling on the Silk Roads in the first century, Buddhism took root in China beginning in the third century, catering to the rising spiritual need of the Chinese as chaos set in during the period of disunion. Over time it gradually mingled with the indigenous teachings, mainly Daoism, to develop distinct Chinese characteristics. Chinese Buddhism was subsequently spread to Korea, Vietnam, and Japan and remained an important defining factor in the continuous transformation of the cultures in all these societies.

Japan's Position in the China-Centered World System to 1000 CE

Although Japan is an island country, it developed historically as part of a larger China-centered world system. Beginning in Han times (206 BCE–220 CE), chiefdoms and states in the Japanese islands, the Korean Peninsula, and elsewhere were bound to the central kingdom (China) and to each other by political and military interactions as well as flows of information and material goods. These external connections had a decisive impact on the development of Japanese society in the period through 1000 CE.

China was historically more populous, more powerful, and more socially and culturally advanced than other regions in East Asia. China's immediate neighbors tended to view it as both a threat and a role model and to view each other as rivals to be outdone. The process of state formation along the Chinese periphery can be described as one of competitive emulation among peer polities in the shadow of Chinese civilization.

The language of this competition was largely determined by the Chinese concept of world order. Partly out of ethnocentrism but also partly because of China's objectively preeminent status, Chinese leaders believed that their country was inherently superior to other states. In their view, diplomatic relations with other states were an expression of the hierarchical world order, with foreign leaders sending official missions to China in order to present tribute.

➤ HAKATA, GATEWAY TO JAPAN

Kyushu Island, and particularly the area around Hakata Bay, historically served as Japan's front door. Situated just 160 miles southeast of Pusan, South Korea, Hakata lies on the shortest and most convenient route between Japan's early capitals and the Asian continent. As such, Hakata was a natural locus for international and intercultural exchange. It was also a natural focus of attention for Japanese political authorities, who sought to control transborder interactions both for reasons of security and in order to monopolize the wealth and prestige accruing from diplomatic and commercial ties with other lands.

Hakata first came under the control of Japan's rulers in the sixth century CE following a brief war of secession by a Kyushu strongman, Iwai. During the seventh-century Korean unification wars, Hakata became a command post for Japanese military operations. After Japan's 663 defeat, an office named Dazaifu was established near Hakata. Dazaifu was responsible for coastal defense and for monitoring the arrival of foreign visitors. The number of such visitors increased substantially from the ninth century, when Chinese and Korean merchants began visiting Japan to sell exotic foreign goods. After the twelfth century government officials lost control of the trade, and Hakata became a thriving commercial entrepôt.

—Bruce L. Batten

Foreign leaders, far from rejecting the premise of Chinese superiority, were frequently enthusiastic participants in the China-centered world order. This was certainly true in the Japanese islands, from which the first recorded tribute mission to China was sent in 57 CE. Numerous other missions were sent in the early centuries CE, most famously by Queen Himiko in the third century and by the so-called Five Kings of Wa in the fifth. ("Wa," or "Wo" in Chinese, referred to the western part of what is now Japan.) These missions were motivated by the desire for Chinese titles (e.g., king of Wa) and prestige goods (e.g., gold seals, mirrors, etc.), both of which were essential to the political legitimacy of Japanese rulers. No stable, unitary state yet existed in the Japanese islands,

and leaders needed all the help they could get in their struggle for domestic supremacy.

The overseas concerns of Wa leaders also extended to Korean kingdoms such as Koguryo, Paekche, and Silla. The Five Kings of Wa, for example, sought Chinese titles granting them authority over various parts of Korea, again out of the desire for prestige and legitimacy. For the same reason and also to obtain needed cultural goods and raw materials (e.g., iron), Wa leaders pursued direct contacts with Korea, most closely with the southwestern kingdom of Paekche.

The international situation in East Asia heated up considerably with the emergence of a unified, expansive empire in China under the Sui dynasty (581–618) and the Tang dynasty (618–907). Chinese expansion had a ratcheting effect on competition among the various Korean kingdoms and Wa. The result was the Korean unification wars in which Silla, aided by Tang, vanquished the other Korean kingdoms and gained control of the peninsula in 668. Wa, which sided with Paekche, suffered a major defeat at the hands of Silla and Tang in 663. The pervasive atmosphere of competition and foreign crisis gave Wa leaders the motivation and means to pursue domestic political reforms culminating in the emergence of a stable, centralized state (newly christened Nihon, or Japan) in the late seventh and early eighth centuries.

During the eighth and ninth centuries Japan remained politically linked to the rest of East Asia but from a position of greater strength than before. Japanese leaders continued to send ambassadors to China but no longer sought tributary status, which was now perceived as demeaning. Meanwhile, they strove to create an alternate Japan-centered world order in which Silla, and later Parhae (also known as Bohai), a Manchurian kingdom that sent its first embassy to Japan in 727, were expected to play the role of tributaries. Not surprisingly, Japan's diplomatic partners did not always share its perception of these relationships. Silla in particular strongly objected to treatment as a Japanese tributary, and relations between the two countries were notoriously rocky.

Tang, Silla, and Parhae all fell in the early tenth century, after which Japan entered a long period of self-imposed diplomatic isolation. Japa-

nese rulers were secure in their rule and no longer in need of support from abroad. Furthermore, exotic foreign goods were now available through commercial as well as diplomatic channels. Chinese and Korean traders first began visiting Kyushu in the early ninth century, and by the early tenth century they had completely supplanted diplomats as the primary medium of international contact between Japan and the Asian mainland. Japan remained tightly linked to China and Korea but only in cultural and economic terms, not political or diplomatic ones.

■ Introduction: South and Southeast Asian Wars

During this era, wars in India and Southeast Asia were commonly fought between forces, which by modern standards may have been numerically small but as a percentage of the existing populations were large at least in Southeast Asia. Horse cavalry were less numerous than in China or the west, but elephants were widely used. The most effective weapon used in India was bamboo or sometimes steel longbow that could shoot arrows with enough force to penetrate armor and stop cavalry charges by invaders from central Asia.

In this introduction, we will discuss conflicts in five areas:

- 1) Northern India, including the Indus and Ganges valleys
- 2) The Deccan, or central India
- 3) Southern India, including the southern third of the peninsula plus the island of Sri Lanka
- 4) Mainland Southeast Asia
- 5) Island Southeast Asia

In northern India, the most significant conflicts, after the establishment of the Gupta empire, were those caused by the invading Hephthalites, or Huna (White Huns). The Hephthalites were “barbarian” invaders from central Asia who had fought long wars with the Sassanian

Persians and occupied Bactria (Afghanistan). From 450 to 528 they regularly swept through the passes to raid the northwest and the Ganges Valley. Although some sources claim that the Hephthalites temporarily toppled the Gupta empire, an Indian force decisively defeated the invaders, ending their menace. After the defeat of the Hephthalites, a series of confused “feudal” wars descended on northern India until Harsha Verdhanta united northern India in 606. Harsha’s 41 years of rule were filled with frequent warfare while he extended his realm to include territory from Gujarat to northern Bengal. Harsha failed in his attempt to extend his empire south, when he was soundly defeated on the banks of the Narmada River by Pulakesi II, ruler of the Chalukya empire of the Deccan. When Harsha died in 647, northern India again devolved in localized feudal wars.

In 711–712, forces of the Umayyad caliphate from Syria invaded and conquered Sindh, a province at the mouth of the Indus River. In 738, Muslim advance in India was stopped at the Battle of Rajasthan, when a force of Rajputs, led by the Pratihara king Nagabhata, destroyed an Arab army, driving the Muslims back across the Indus River. This Muslim defeat stopped the Muslim advance into India for nearly three centuries. This was six years after

SOUTHEAST ASIA, CIRCA 700

the Muslim advance in western Europe at the Battle of Tours.

From the middle of the eighth century to the middle of the tenth century, two north Indian empires (that of the Pratiharas, centered in Gujarat, and that of the Palas in Bengal) and one central Indian empire (that of the Rashtrakutas) struggled for supremacy in the Ganges Valley. The focus of their conflict was the city of Kannauj, which had been Harsha's capital. The forces of these three were nearly evenly matched, so the city changed hands several times in these two centuries.

The Chalukyas ruled most of the western Deccan from the middle of the fifth century to 753, when they lost out to the Rashtrakutas. As we have seen, the Chalukyas intervened in northern affairs to stop Harsha's empire from expanding south. The Chalukyas also waged frequent wars against the Pallavas in southern India and the Rashtrakutas in the Deccan until the Rashtrakutas crushed the Pallavas in 753. The Rashtrakutas then ruled the western Deccan and, as we

have seen, contested for supremacy in the Ganges Valley until their downfall toward the end of the tenth century.

At the southern end of the Indian peninsula, the Pallavas contested with the Pandyas, the Cholas, and sometimes the Cheras for dominance. The Cheras, whose strength was situated in the Malabar (western) coast, were somewhat peripheral in this contest. The Pallavas were the dominant power in southern India for several centuries after the sixth century (chronology in early medieval southern Indian political history is somewhat indeterminate) until the Cholas defeated them in the mid-ninth century. The Pandyas were concentrated on the southern tip of the peninsula, and the Cholas too subdued them in the ninth century.

On the island of Sri Lanka, the enduring conflict was between the native Sinhalese kingdoms and the Pandyas and Cholas, who invaded and occupied the northern part of the island numerous times. The Cholas sent naval expeditions to points on the coast of the Bay of Bengal and into

the islands of the Indonesian archipelago repeatedly for three centuries, until 1250.

Toward the end of the eighth century, Javan pirates attacked the capital of Cambodia and seized the king. A successor drove the Javan out and moved the capital to Angkor in 802. The Khmer kingdom of Cambodia was the leading state in mainland Southeast Asia. The Khmers waged wars against the Mon kingdoms of Dvaravati and Lophuri (in present-day Thailand), which they sometimes reduced to tributary status. But perhaps the most persistent conflict was with the kingdom of Champa (on the central and southern coast of present-day Vietnam). Several times Khmer forces occupied the Cham capital, but sometimes Cham forces defeated Khmer armies. The Khmer-Cham conflict persisted for nearly a millennium, from the sixth century to nearly the sixteenth century.

Champa also had another persistent antagonist, Vietnam. During this era, Annam, as Vietnam was then known, was a province of China. The Chinese in Annam conducted frequent campaigns against Champa. China's Sui dynasty, around 600 CE, sent a force that temporarily occupied Champa's capital. After Vietnam won its independence from China in the tenth century, successive Vietnamese dynasties continued the conflict until they destroyed the last Champa kingdom in the sixteenth century.

In the Irawaddi Valley, where modern Myanmar is today, the Pyu kingdom of Shrikshetra experienced frequent invasions from the aggressive Nanzhao kingdom, located in the modern Chinese province of Yunnan. Nanzhao reduced Shrikshetra to a vassalage and, when the people revolted (832), destroyed the Pyu capital, Hmawza, and transported the people as slaves to the Nanzhao capital on Lake Dali. Nanzhao also waged frequent wars with Burmese Pagan after 800.

In the Indonesian archipelago, Buddhist Srivijaya and the Hindu kingdoms in central Java clashed until the Hindu kingdoms drove Srivijaya's allies from central Java.

Mainland Southeast Asian Wars

For the period under consideration, three major political centers can be identified: central Burma inhabited by the Pyu, the lower Menam (Chao Phraya) basin of the Mon people, and the region comprising the Mekong Valley and Vietnam. The latter two areas have to be taken together, as they formed a single arena fiercely contested among the Khmer, Cham, and Viet peoples. Wars and interaction with the Southeast Asian mainland have to be seen in connection to their relations with the outside world, mainly India and China. For a long time, early Southeast Asia has been regarded as being Indianized or Hinduized, two terms denoting Indian influence in Southeast Asian culture, discernible in the fields of religion (Hinduism, Buddhism), language, or astronomy. However, on the one hand the size of Indian influence has to be set against the influence exerted by the Chinese, as China was a close neighbor and therefore a much more significant political and economic power. On the other hand, the external influence of both India and China have to be set against the autonomous agency of the Southeast Asian people themselves, who could decide between the offers of two cultures rather than simply submitting to them.

Accordingly, Southeast Asian rulers have repeatedly sent diplomatic missions to the Chinese emperors, which not only brought them recognition but usually trade concessions too. Military conflicts between the Chinese emperors and Southeast Asian rulers rarely occurred; apart from the continuous Chinese suzerainty over the Red River plains of northern Vietnam, which lasted for the whole period, the major disturbances were created by the Yunnan-based Nanzhao, who in the eighth and ninth centuries CE frequently raided Southeast Asian territories.

➤ SOUTHEAST ASIAN WAY OF WAR

Classical Indian texts such as the *Mahabharata*/*Ramayana*, the *Arthashastra*, and some late Vedic texts mention the “four parts of the army” (infantry, cavalry, elephantry, and chariots). However, only the former three are to be found in Southeast Asian armies of the same period. Instead of chariots, war boats were better suited for Southeast Asia’s many rivers. Success in a war depended as much on a ruler’s ability to muster a large number of foot soldiers as it did on his ability to raise and maintain sufficiently trained war elephants. Manned with bowmen and a mahout and often surrounded by infantrymen to protect their vulnerable legs, elephants were the “tanks” of the military equipment in pre-modern Asia.

—Tilman Frasch

In addition to these intra-Asian connections, the Southeast Asian mainland was linked to the outside world by way of trade. Much evidence for long-distance trade comes from Oc-eo, an emporium in the western part of the Mekong Delta flourishing since around the second century CE. Excavations have yielded a broad spectrum of goods and artifacts originating from the Mediterranean, Persia, India, and China.

The period witnessed many conflicts and feuds among the rulers and headmen of Southeast Asia, most of which seem to have gone unrecorded. The major exception appears to be the Cambodian-Vietnamese struggle that intensified with the rise of Angkor after 800 CE. The one area affected by this struggle was the long coastal strip of what is now Vietnam. Its northern part had earlier come under Chinese domination, and it was not before the eleventh century that the Vietnamese rulers of the Ly dynasty could contain the Chinese temporarily. The Vietnamese were in turn challenged by the Cham people, who ethnically and linguistically belong to the Malayo-Austronesian peoples. The Chams repeatedly defeated the Vietnamese, but with the rise of Angkor in the west, they became themselves sandwiched between the Vietnamese and the Khmers. The Khmers invaded Cham territory for the first time in the mid-tenth century, although the major wars between the two powers were

fought only in the twelfth century, when the Chams first conquered Angkor and were then defeated by the Khmer. A panel from Angkor Vat, which shows that the Chams invaded the country on ships, actually comes from the twelfth century but may reflect an earlier form of warfare as well. In fact, once the hills separating the Vietnamese coast from the catchment area of the Mekong are crossed, the Mekong and Thonle Sap rivers form natural waterways that allow easy access into Angkor. Numerous examples, ranging from Javanese raids on Vietnam and Cambodia to the campaign of a South Indian armada against Sri Vijaya around 1025 CE, illustrate that ships were capable of transporting armies, including horses and elephants.

The Javanese raids of the Southeast Asian mainland, which took place in the eighth and ninth centuries CE, seriously affected its political developments. It seems that the Javanese temporarily succeeded to establish a lasting overlordship in the conquered coastal areas. The relocation of the Khmer capital from the coastal area around Oc-eo to Angkor in the interior could have resulted from the expectation that it would in the future deny Javanese warships easy access to the capital.

Angkor’s rise to dominance over the mainland after 800 CE was based on territorial expansion, mainly into the western mainland. This affected first the settlements of the Mon people in the Menam basin, known under the name of Dvaravati. With Angkor expanding, the Mons began to migrate to northern Thailand (Lan-na) and very likely to Lower Burma (Pegu) as well. The migration of the Mons into Burma seems to have been a predominantly peaceful affair, although it added to the pressure put on the Pyu people living in large city-states in central Burma. Although it is uncertain whether we can assume the existence of a single Pyu state, it seems clear that the century between circa 730 and 830 CE was a period of crisis for the Pyu. In addition to the immigrating Mons, the Nanchao of Yunnan repeatedly invaded Upper Burma and on one occasion conquered a major Pyu city, abducting most of its inhabitants. The third party to put pressure on the Pyus was the ethnic Burmans who, having migrated from Inner Asia, finally made their way into central Burma. Becoming sedentary, they

mixed with the Pyus (to whom they appear to be linguistically related), taking over the latter's culture of wet-rice cultivation, city building, and very likely Theravada Buddhism as well. After a dark age of approximately two centuries, the former Pyu settlement of Pagan was to become the capital of the first kingdom of Burma.

Finally, one instance of religious intercourse deserves mention even though it may not qualify as conflict in the narrow sense. Buddhism had been known on the mainland for a long time, but since around 800 CE a new process began to direct the region toward its present shape. While Buddhism disappeared completely from its Indian homeland, the religion became firmly rooted in the societies of mainland Southeast Asia, where Theravada prevailed, and insular Southeast Asia (mainly Java), where Mahayanist and Tantric traditions dominated. Ultimately, Theravada became the mass religion of the people on the mainland, but where Theravada failed to succeed, Buddhism also declined and eventually disappeared altogether.

Island Southeast Asian Wars

Seen from the sea, insular Southeast Asia can be described as the area circumferencing a major maritime highway, sometimes called “the silk roads of the sea.” In effect, this was a set of sailing routes that connected China to the Indian Ocean and the Red Sea. Crossing the Bay of Bengal in the west, this route ran through the Malacca Straits to the southern tip of the Malay Peninsula, where it bifurcated. The northern branch headed straight north toward the southern fringes of the Mekong Delta and then ran

along the mainland coast to China. The southern branch went farther east at first along the north coast of Java. There it split again, taking ships either farther to the Spice Islands or heading north along the coast of Sulawesi Island.

The landscapes along these routes were highly disparate in terms of language and ethnicity, although Malayan dialects seem to have served as a kind of lingua franca (common language). Obviously, the region was open to all kinds of outside influences in which two areas stand out. For a long time, Southeast Asia has been seen as Indianized or Hinduized for the highly visible elements of Indian culture in the religion (both Hinduism and Buddhism), language, or astronomy. This alleged superiority of Indian culture, however, has to be set against Chinese influence, which became manifest in the many tribute missions that Southeast Asian rulers would habitually send to the Chinese emperors. By way of these missions, Southeast Asian rulers gained political recognition combined with trade privileges. The tradition of sending diplomatic missions to the Chinese court also indicates that the question of Indianization versus Sinicization ultimately depends on the autonomous agency of the Southeast Asian sovereigns and people, who could choose from either side what suited their interests best.

Most of the intercourse taking place in the archipelago would have been of a peaceful nature, consisting especially of trade and all forms of economic exchange. Accordingly, evidence for trade with virtually all the rest of the world has been found at many port sites of Southeast Asia. Along with this, trading communities including Arabs, Jews, Persians, Armenians, Indians, and Chinese came to the area and occasionally settled there as well. A case in point is the South Indian trading associations such as the Nanadeshis (“those trading to foreign countries”) whose inscriptions, artifacts, and religious monuments were found all over the archipelago.

The Southeast Asian seascape favored waterborne intercourse and traffic involving a broad variety of boat types. The most common Southeast Asian type usually possessed outriggers and had two masts in addition to oars. The biggest ships, which had a burden of several hundred tons, may have been the Chinese *jongs* and the
